CAUSATION OF ECZEMA, URTICARIA AND ANGIONEUROTIC EDEMA

PROTEINS OTHER THAN THOSE DERIVED FROM FOOD: STUDY XVIII *

I. CHANDLER WALKER, M.D.
BOSTON

n 1912, Talbot and Towle,[1] from a study of the ols of eczematous patients, concluded that foods yed a considerable part in the causation of eczema; fats and starches as well as the proteins were conned. In 1916, Blackfan[2] called attention to the ociation of eczema with asthma in children who e sensitive to foods. McBride and Schorer[3] found in predisposed persons certain food proteins sed urticaria and erythema. White[4] noted the anaic phenomenon in eczema, and a year later[5] he no longer doubted the fact that food conts (protein, fat and carbohydrate) play some the abnormal composition of individuals with chronic rebellious eczema. Urticaria fol the ingestion of certain foods and the injection m is a common occurrence. Since it would be an established fact that foods may and do eczema and urticaria in some persons, cases ting such instances will not be given here. Sufo say that in our study of bronchial asthma we equently observed the association of eczema hma in patients who were sensitive to various oteins, and we have definitely proved in some at urticaria was caused by food proteins.

hi paper I shall present instances in which rticaria and angioneurotic edema were proroteins which are not foods, but with which mately come in contact throughout life, o far have not been recognized as possible ese conditions: four cases of eczema, two ere caused by the proteins of horse dany the pollen of timothy and one by the pollen of ragweed; five cases of urticaria, two of which were caused by horse dandruff proteins and three by ragweed pollen, and three cases of angioneurotic edema, caused, respectively, by timothy pollen, flaxseed and ragweed pollen. With the exception of one patient who had hay-fever, all of the patients had bronchial asthma, and the asthmatic condition was caused by the same proteins that also caused the eczema, urticaria and angioneurotic edema.

PROTOCOLS OF PATIENTS WITH ECZEMA

CASE 1.—W. P., aged 11, had bronchial asthma and eczema continuously since he was 1 year old. He could not ride behind a horse without having asthma. The eczema was dry and scaly, and was present all over his body with the exception of his face.

Cutaneous reactions were positive with the pollen of ragweed and with the proteins of horse dandruff. The alkali metaprotein and the peptone of horse dandruff gave positive reactions in a dilution of 1:1,000 and the coagulated protein gave a positive reaction in a dilution of 1:10,000.

The patient was treated subcutaneously at weekly intervals with gradually increasing amounts of horse dandruff coagulated protein in a dilution of 1:100,000. After a few such treatments the patient noticed that when he bathed there was much less desquamation all over his body, and his forearms were practically free from eczema. Riding behind horses no longer caused asthma.

CASE 2.—M. T., a girl, aged 15, had bronchial asthma for nine years. Although she had asthma all through the year, it was worse in summer, when she also had hay-fever. She had eczema on the hands every summer.

Cutaneous tests were positive with ragweed pollen in a dilution of 1:5,000, and with horse dandruff peptone in a dilution of 1:1,000.

After a series of treatments with ragweed pollen in gradually increasing amounts, the patient had no asthma, hay-fever or eczema during the ensuing summer. Following the completion of the ragweed treatments, a series of subcutaneous injections with horse dandruff peptone were given. During twelve weekly injections of the peptone in a dilution of 1:10,000, no untoward symptoms were noted. The dilution of the peptone was then increased to 1:1,000, and each week the amount of this dilution was slowly increased. After a few of these treatments the patient began to have eczema on her forehead; this gradually spread and resisted all medication. It was thought advisable to omit treatment with the peptone and all medication for the eczema. After one week there was marked improvement in the eczema, and two weeks later the eczema had practically disappeared.

CASE 3.—C. S., a girl, aged 10, had asthma since she was 2 years of age. The patient had eczema continuously between the ages of 1 and 2, and she had had it off and on ever since.

Cutaneous tests were positive with the proteins of horse dandruff in dilutions of 1:10,000 and with the pollen of timothy in a dilution of 1:500.

The patient was treated subcutaneously fourteen times in as many weeks with horse dandruff alkali metaprotein, first a 1:100,000 dilution, later a 1:10,000 dilution and finally a 1:1,000 dilution being employed. During this treatment the

patient was free from symptoms, including asthma and eczema. In anticipation of the pollen season, the patient was given during April and May subcutaneous injections of timothy pollen, first in a dilution of 1:1,000, then 1:500 and finally in a dilution of 1:100; this was in conjunction with the horse dandruff treatment as outlined above. After five doses of the timothy pollen, the patient complained of very troublesome eczema, which was similar to what she had had previously. She said that it began to appear after the third timothy injection, that it was gradually getting worse, and that it was most marked the next day after the injection. The eczema was very itchy, scaly and dry, and it was present on the back and under the knees and at the bends of the elbows in the antecubital fossae. Further injections with the timothy pollen were discontinued, but the horse dandruff treatment was continued. The eczema gradually disappeared; in two weeks the patient's back was free from eczema, and in four weeks the knees and arms became free. The patient was still being treated with large doses of horse dandruff protein.

Case 4.—A woman, aged 65, always had bronchitis and eczema periodically; the eczema appeared each year during the latter part of the summer, and at this time she had bronchial asthma.

Cutaneous tests were positive with ragweed pollen only.

Previous to the cutaneous tests the patient's physician had considered ragweed pollen as a cause of eczema in this case, since she was free from it, provided she kept out of her garden, which was surrounded by ragweed. After the positive test had been obtained with ragweed pollen, the patient was allowed to go in her garden with her hands and arms covered with cloth. In spite of this protection, during the latter part of August when the ragweed pollen is being shed, the patient had a little eczema. She was then not allowed to go into her garden at all, and the eczema entirely disappeared for the remainder of the summer.

In the first case there would seem to be little doubt that horse dandruff played a part in the causation of eczema, since improvemnt in the eczema was quite rapid during treatment with small amounts of horse dandruff protein. The same was also true of the asthmatic condition. Judging from our experience with Case 2, we should anticipate that sooner or later when large amounts of horse dandruff protein are given an amount will be reached which will make the eczematous condition worse. In Case 2 there can be no doubt that the subcutaneous injections of horse dandruff protein caused the eczema, since it appeared during the treatment and since it disappeared when the injections were discontinued. Small amounts of the protein, however, did not cause eczema; therefore it may be possible to treat eczema satisfactorily with very small desensitizing doses of the offending protein. The two cases represent two different channels of exposure to the protein; the first patient had eczema from natural exposure to horse dandruff, and the second patient had eczema when the protein was introduced beneath the skin. In other words, in the first case the offending agent was outside the body, and in the second case it was inside the body, thus simulating food in the causation of eczema. In Case 3 there can be no doubt that timothy pollen protein caused eczema, since the eczema appeared during subcutaneous injections of the pollen, it was worse soon after each injection, and it disappeared soon after the injections were omitted. Horse dandruff proteins played no part in the causation of eczema, since injections of these proteins were continued while the eczema was clearing up. It is quite probable that previous attacks of eczema were caused by exposure to timothy pollen. In Case 4 it is quite evident that ragweed pollen caused eczema through natural exposure by contact with the pollen.

PROTOCOLS OF PATIENTS WITH URTICARIA

Case 5.—F. I., a boy, aged 7, had bronchial asthma s he was 8 months old.

Cutaneous tests were positive with horse dandruff pep and coagulated protein in dilutions of 1:10,000, and were doubtfully positive in a dilution of 1:100,000.

The patient was given at weekly intervals six subcutan. injections with horse dandruff peptone in a dilution 1:1,000,000; the amount of this dilution was increased each treatment, and no untoward symptoms resulted. dilution of the peptone was then increased to 1:100,000, no symptoms followed 0.1 c.c. of this dilution. A week the same dose was repeated, and in a few hours the pat developed large, white, very itchy urticarial wheals his whole back; these persisted for only a few hours. A w later the same dose was again repeated but without sy toms, and since then the amount of the dilution has b gradually increased without producing symptoms, and patient has been free from asthma.

Case 6.—M. S., a girl, aged 13, had bronchial asthma sin she was 1 year old. During the first year of age she h eczema, but this disappeared when asthma began. The patie had urticaria after drinking milk.

Cutaneous tests were positive with the proteins of ric milk and mackerel, and with all three proteins of horse da druff in dilutions of 1:100, and with the coagulated protei in a dilution of 1:1,000.

The patient was given subcutaneously 0.1 c.c. of the coag lated protein in a dilution of 1:10,000. The next mornin there were present all over her body raised, itching blotche which the patient's mother called hives. A week later same dose was repeated without producing symptoms, an further increase in the dose produced no symptoms.

Case 7.—W. P., a man, aged 44, had asthma for fifte years and hay-fever for ten, both chiefly in the summe months, from the middle of August to the first of October He had winter bronchitis.

Cutaneous tests were *positive with the pollen of ragweed in a dilution of 1:5,000, and of goldenrod in a dilution of 1:100; higher dilutions of these pollens failed to give reactions.*

The patient was thus treated subcutaneously at weekly intervals with ragweed pollen: 1:10,000 dilution, 0.1 c.c.; 1:5000 dilution, 0.1, 0.2 and 0.3 c.c.; 1:1,000 dilution, 0.1 and 0.2 c.c., and 1:500 dilution, 0.1 and 0.2 c.c. A few minutes after the last injection, large, raised, white, very itchy wheals appeared over the patient's whole body; they disappeared in a few hours. Subsequent weekly injections of 0.2 and 0.4 c.c. of ragweed pollen in a dilution of 1:500 caused no untoward symptoms.

Case 8.—J. M., a boy, aged 12, had asthma since he was 1 year of age. He had eczema from infancy up to a few years ago, when it disappeared and has not since returned.

Cutaneous tests were positive with ragweed pollen in a dilution of 1:500 and with the proteins of horse dandruff in dilutions of 1:100; higher dilutions of the pollen and of the dandruff proteins were negative.

A subcutaneous injection of 0.1 c.c. of a 1:1,000 dilution of ragweed pollen was followed the next morning by urticarial wheals over the whole body. Three days later, 0.1 c.c. of a 1:500 dilution of the pollen was followed the next morning by a much less extensive urticaria. Subsequent injections at three day intervals of 0.2 c.c. of a 1:500 dilution of the pollen and 0.1 and 0.2 c.c. of a 1:100 dilution of the pollen caused no untoward symptoms. A series of injections with the proteins of horse dandruff also failed to produce urticaria.

Case 9.—B. S., a housewife, aged 46, had the summer type of hay-fever and asthma for nine years.

Cutaneous tests were positive with the early and with the
late pollens. Timothy pollen was positive in a dilution of
1:100 and doubtful in a dilution of 1:500, red top pollen
was doubtful in dilution of 1:100, and ragweed pollen was
positive in a dilution of 1:100 but only slightly positive in a
dilution of 1:500.

The patient was given a series of subcutaneous injections at weekly intervals with timothy pollen in dilutions of 1:500

and 1:100 without symptoms. The patient was then similarly treated with ragweed pollen in 1:1,000 dilution, 0.1, 0.2 and 0.3 c.c., and in 1:500 dilution, 0.1 c.c., without producing untoward symptoms. A week later, 0.2 c.c. of 1:500 dilution was followed in a few hours by an attack of asthma and by urticaria which continued for only a few hours. Treatment, however, was continued as previously with 0.3 and 0.4 c.c. of a 1:500 dilution and with 0.1 c.c. of a 1:100 dilution without producing symptoms.

In the foregoing protocol the first two patients, Cases 5 and 6, both developed urticaria following subcutaneous injections of horse dandruff proteins. It is difficult to explain why in Case 5 the second dose of 0.1 c.c. of protein caused urticaria when only a week previous the same dose had failed to do so. The theories of antianaphylaxis would not seem to obtain in such a case. Rackemann[6] has recently reported an instance in which such theories failed. The other three patients, Cases 7, 8 and 9, developed urticaria following injections of ragweed pollen. In Cases 7 and 9, the theories of antianaphylaxis fail. Although such experiences are neither usual nor serious, nevertheless great care should be employed in attempting to desensitize patients in order to avoid more serious results. It is interesting that in Case 9 timothy pollen should fail to produce urticaria, whereas ragweed pollen did cause urticaria, since the patient by skin reaction was equally sensitive to the two pollens.

PROTOCOLS OF PATIENTS WITH ANGIONEUROTIC EDEMA

Case 10.—A physician, aged 28, had the summer type of hay-fever for seven years, and during the past winter he had slight asthmatic attacks with colds. The patient's mother had hay-fever, and his two children had urticaria after eating strawberries and lobster.

Cutaneous tests were positive with all of the common pollens and with alcoholic extracts of horse dandruff and guinea-pig hair. Timothy pollen gave a positive test in a dilution of 1:1,000 but no higher.

The patient had no ill effects following two subcutaneous injections of timothy pollen in a dilution of 1:5,000. A week later by mistake he injected 0.1 c.c. of a dilution of 1:500 instead of 1:1,000, as should have been done. Following this injection the patient had the following symptoms, which will be given in detail since he observed himself closely: Ten minutes after the injection, the patient's eyelids itched severely. This was quickly followed by suffusion of the face and neck; the latter rapidly became much swollen, necessitating the rapid removal of the patient's collar. The nares and nasopharynx became greatly swollen, thus making respiration through them difficult. His face became turgid and swollen, and the swelling of his face was so marked that it was on a level with his nose. The swelling of the eyelids closed his eyes. The suffusion extended rapidly over his chest and body, with intense itching, and shortly urticarial wheals developed. The wrists and hands soon became involved, but the arms and legs remained free from wheals. All of the foregoing symptoms, with the exception of the edema, disappeared in three hours. A few hours later, the patient had intense cramplike pains in the abdomen, and extreme tenesmus which was not relieved by going to stool. During this train of symptoms the patient's pulse rate was 120 per minute, his temperature was normal, and his respiration was rapid and labored; his blood pressure was not taken. He had considerable headache throughout the night, and he was restless and irritable. The next morning his face and eyelids were still badly swollen, and he felt somewhat prostrated, although he was not prevented from working.

Case 11.—A nurse, aged 28, had bronchitis and asthma from childhood. Recently while making a flaxseed poultice the patient had an attack of coughing, sneezing, watering of the eyes, and asthma.

Cutaneous tests were positive with the protein of flaxseed.

The patient was given subcutaneously 0.1 c.c. of a 1:10,000 dilution of flaxseed protein. Five minutes later the patient began to cough and choke, and five minutes later still she was unable to walk because of extreme dyspnea. Her head became very hot, her neck began to swell so that she had quickly to remove her collar, her face became so swollen that both eyes were closed, and she began to itch terribly. Her head itched severely, her ears felt like bursting, her heart felt queer, she was sick at the stomach, respiration was difficult, and on the whole she felt impending death. She was very cyanotic, and urticarial wheals developed over the upper part of her body. The urticaria soon disappeared from the upper part of the body only to appear over the lower part of the body; but in an hour she was free from urticaria. During the height of the disturbance a subcutaneous injection of epinephrin (adrenalin chlorid, 1:1,000, Parke, Davis & Co.) relieved the head and earache and the dyspnea. The patient was unable to sleep because of severe gas pains in the abdomen. The next morning she felt normal.

Case 12.—F. V., a woman, aged 44, had asthma for seventeen years only in the summer time from the middle of August to the first of October. In childhood she had hay-fever and eczema.

Cutaneous tests were positive with ragweed pollen in a dilution of 1:500, and a dilution of 1:1,000 gave a doubtful reaction.

The patient was given a subcutaneous injection of ragweed pollen in a dilution of 1:1,000; 0.1 c.c. was given. A few minutes later she had an attack of sneezing, wheezing, ringing of the ears, running of the eyes and nose, and her face suddenly became swollen and her collar had to be quickly removed. A few hours later she was normal.

In the foregoing protocols, Patients 10 and 11 had typical angioneurotic edema, which, according to Osler, includes urticaria and intestinal cramps. In Case 10, angioneurotic edema followed too large a subcutaneous dose of timothy pollen, and in Case 11 it followed a very small dose of flaxseed protein; in fact, the amount of flaxseed protein was probably much less than that which may be readily absorbed from its application as a poultice. It is probable that the patient became sensitized to flaxseed protein through the frequent application of such poultices, since as a child she remembers such medication for her bronchitis. Patient 12 had marked swelling of the face, neck and throat following a small injection of ragweed pollen, but the reaction was much less marked than in the two preceding cases. Such experiences well illustrate the great care that should be employed in the desensitization of persons with proteins to which they are sensitive.

CONCLUSIONS

The proteins of horse dandruff, ragweed and timothy pollens may cause eczema both from external exposure and internal injection in predisposed persons. As we have found it to be with food proteins, so it is with the foregoing proteins: Eczematous patients tolerate very small doses of the offending protein and the eczema seems to improve; but a slight increase above this small amount makes the eczema worse. The amount of protein that benefits eczema is too small to prevent asthma, and the amount of protein that benefits asthma makes the associated eczema worse. Therefore, desensitization for eczema, if such is possible, must be a very slow and cautious process, even more than for asthma.

[6] Rackemann, F. M.: Interesting Reactions Incidental to the Treatment of Two Cases of Bronchial Asthma, The Journal A. M. A., Sept. 15, 1915, p. 889.

The negroes of the Columbus Hill district, in the great majority of instances, have emigrated from the West Indies, only a few having come from the southern part of the United States. Most of them have been here a few years, giving the islands of St. Kitts, the Barbadoes and St. Croix as their places of birth. It appeared worth while to inquire into their habits and diet before they emigrated to this country, and to compare these with their mode of life in a great metropolitan city under different climatic conditions. No more striking contrast could have been found. In the West Indies they lived an outdoor life, their diet consisting mainly of vegetables and fruit. They stated that they frequently ate two or three kinds of vegetables at a meal, and partook of them always fresh—never in a dried or canned state. The variety of vegetables was also considerably greater than we have in New York City. In addition to peas and beans, spinach, etc., they mentioned yams, breadfruit, "tanniers," eddoes, watercress and okra as forming frequent articles of food. Many of these vegetables grew in their own gardens, or were brought to the town from the suburbs and sold at what seem to us nominal prices. Just as the dietary was rich in vegetable food, so was it also in fruit, which they consumed once a day or oftener.

It is probable that a dietary as deficient as that of this urban community must affect the body tissues. The question may well be raised whether this would not be true to a greater extent among a people accustomed to have fresh food in abundance. It is difficult to state in chemical terms the exact deficiency in this diet. For calcium and other salts, however, we depend largely on milk, vegetables and fruit, and it is in all these foods that the dietary we have outlined is markedly lacking. It would seem certain that these women, and probably others who are living in the large cities of the North, are receiving an amount of calcium which is close to their minimum requirement.

There is a hypothetic aspect which suggests itself in relation to this subject. As is well known, the negro race is particularly subject to rickets. In fact, almost all the negro children in New York City, whether nursed or artificially fed, seem to have this disorder to a greater or less extent. The nature of rickets and the cause of this racial susceptibility remain illusive and unsolved problems. It is known, however, that the negro in the tropics does not suffer from rickets. We have made direct inquiries of physicians in Jamaica, Cuba, Panama, Trinidad and the Bahamas, and received unanimous reports that this disease has been rarely encountered in their experience.[3] There are many etiologic factors to which the difference in the incidence of rickets in the tropics and in the North may be ascribed. It is a mooted question, one which has occupied pediatric attention for many years, but which cannot well be discussed at this time. We must take into account the contrast in the northern negro's mode of life, as well as the change in the climate. This, however, does not exclude the possibility that the marked difference in the food also plays a part. The fact that this race has lived on a diet largely composed of fruit and vegetables—foods rich in calcium and in undefined substances present in all fresh vegetable products—and the fact that its dietary has suddenly been changed so that meat becomes one of the principal ingredients, to the virtual exclusion of fresh fruits and vegetables, may well alter the metabolism of the mother and her offspring.

AN EXPERIMENTAL INVESTIGATION OF LIPOVACCINES

AN ADDITIONAL NOTE, WITH A NOTE ON TRIPLE DYSENTERY LIPOVACCINE *

E. R. WHITMORE, M.D.
Lieutenant-Colonel, M. C., U. S. Army
AND
E. A. FENNEL, M.D. (CINCINNATI)
Lieutenant, M. C., U. S. Army
WASHINGTON, D. C.

At the Washington meeting of the Society of American Bacteriologists, in December, 1917, we presented a preliminary note on lipovaccines. In THE JOURNAL, Feb. 16, 1918, we gave the results of vaccination of animals and men with a triple typhoid, a triple dysentery, a pneumococcus, and a meningococcus lipovaccine, and we gave our reasons for thinking the oil suspension would be an advantage in each case.[1] In both of those notes we indicated some of the difficulties that would have to be overcome in order to produce the vaccines on a large scale. We now feel that we have overcome some of these difficulties.

As all of our first series of animals and men are now broken up, and much more comprehensive series are under way on all of the vaccines, we desire to record the final results of our preliminary series of vaccinations, especially with the triple dysentery lipovaccine.

PREPARATION OF THE LIPOVACCINES

Preparation of the Bacterial Mass.—One of the principal points is to get the bacteria from the culture medium into the oil as promptly as possible, and with as little change as possible. It appears that freezing and drying in vacuo accomplish this better than does drying in warm air.

Rogers[2] has shown that when bacteria in milk are frozen and dried in vacuo over sulphuric acid, there is no change in the concentration of substances in the liquid in which the organisms are bathed, and that in lactic bacteria dried that way, from 90 to 95 per cent. of the organisms are alive after drying. He also showed that the number of living organisms was greatly reduced when they were dried by a current of warm air.

---

[3] Dr. J. E. Ker, Kingston, Jamaica, British West Indies, superintending medical officer, wrote: "Rickets, as we know it in infants in large towns, practically does not exist here in Jamaica. Beaded ribs and square heads are of the very rarest occurrence."

Dr. Guiteras, Havana, put our question to Dr. Aballi, a specialist in the diseases of children, who said: "My experience is that colored children in Cuba suffer but little from rickets. Only exceptionally do we meet with a grave form, and the lighter ones are not frequent, with slight epiphyseal enlargements and beading of ribs."

Dr. Guiteras himself wrote as follows: "My impression is the same as Dr. Aballi's. It is interesting to note that in the absence of natural alimentation, much boiled milk is always used."

Dr. W. B. Pierce, Panama, superintendent of the Hospital Santo Tomas, as a result of his experience, having been in the Health Department of the United States government on the Canal Zone and the City of Panama for the past eight years, wrote: "I have yet to see my first case of rickets in the West Indian negro child. My colleagues who have been here much longer tell me that West Indian children down here never have rickets."

Dr. R. Scheult, Colonial Hospital, Trinidad, Port of Spain, expressed the following opinion: "You will be surprised to learn that during my twenty-four years of hospital practice in this colony I have not met a single case of rickets, although hundreds of children are treated in our children's ward every year. This, no doubt, may be attributed to their diet, which consists mainly of vegetables and fruit."

Dr. J. B. Albury, Nassau, Bahamas, wrote: "I do not consider rickets at all a common disease here among negroes."

* From the Department of Pathology, Army Medical School.

[1] Whitmore, E. R.; Fennel, E. A., and Petersen, W. F.: An Experimental Investigation of Lipovaccines, THE JOURNAL A. M. A., Feb. 16, 1918, p. 427.

[2] Rogers, L. A.: The Preparation of Dried Cultures, Jour. Infect. Dis., 1914, **14**, 100.

In the preparation of the lipovaccines, the bacteria are grown on agar in Kolle flasks, and are removed with a vacuum scraper. This scraper consists of a T shaped or Shepherd's crook shaped piece of metal tubing with a narrow slit or multiple holes in that portion which comes in contact with the agar. This scraper is attached to a vacuum pump through a collecting flask; and when passed over the surface of the agar it removes the bacterial growth very thoroughly. In this way large amounts of bacterial material can be collected from the Kolle flasks without the addition of any fluid, and with a minimum of danger of contamination.

The bacterial growth is at once poured into Petri dishes, frozen, and dried in vacuo. If, for any reason, there is any delay in drying, the bacterial material is kept frozen and at constant temperature, and, being in Petri dishes, the material can be put directly into the desiccators without being allowed to thaw.

We have dried our material in glass desiccators and in the metal desiccator devised by Rogers. Metal desiccators for direct circulation of brine from the refrigerating plant are now being installed, and this will make it possible to freeze and dry the bacteria in large amounts.

When the bacterial mass is frozen and dried in vacuo, it makes a flaky mass that readily crumbles to a fine powder. This dried bacterial material is at once incorporated in the oils.

Preparation of the Lanolin and Oil.—We have used lanolin, lecithin and sperm oil for emulsifying the bacteria in the oil before the final dilution with oil.

Any vegetable oil appears to be satisfactory as a vehicle: the oil must not be irritating when injected, and it must not be too rapidly absorbed, but it must be completely absorbed. Olive oil is being used at the present time; though we have used sweet almond oil, castor oil, cottonseed oil, and sesame oil.

Sterilization of the lanolin and oils has received attention. Achard and Foix[3] found that when olive oil was heated high enough to sterilize it in dry air, the oil was changed so that it at times gave abscesses on injection.

We find that these oils, when seeded with *B. subtilis* spores, can be sterilized in the autoclave at 15 pounds for fifteen minutes; and any water they take up will soon settle out. We also find that heating the oil to 90 C. on a water bath for ten hours, as is done by Eimer and Amend, will sterilize.

We have tried sterilization with the halogens. Chlorin sterilizes the oil, but it is difficult to remove the hydrochloric acid which is formed in the process, as the vegetable oils form soaps when an alkali is added. These chlorinated oils also tend to decompose on standing, with the formation of hydrochloric acid.

We find that when powdered potassium iodin is added to olive oil and sweet almond oil, iodin is liberated in sufficient amount to sterilize the oil; and then the iodin is taken up in the oil molecule and no free iodin can be detected. Sweet almond oil is sterilized in about three days; but it requires about ten days to sterilize olive oil. It is necessary to know whether this method of sterilization will affect the antigenic power of the vaccine. Dr. Small is working on this problem.

We are also trying ultraviolet rays in the sterilization of the oil.

For the present we are sterilizing the lanolin and oils in the autoclave at 15 pounds for fifteen minutes, and find this entirely satisfactory.

Mixing the Bacterial Mass with the Lanolin and Oil.—For grinding we are using glass stoppered bottles of large diameter, with steel balls such as are used in ball bearings. We do not find that the glass is ground off to any extent; and when we are able to get bottles of large diameter made of pyrex glass, we believe this will be far superior to porcelain jars with pebbles for this work.

The bacterial mass is ground for forty-eight hours; then enough lanolin to make 10 per cent. in the completed vaccine is added, and the mixture is ground for twenty-four hours; then the oil is added, and this mixture is ground for twenty-four hours.

In using lecithin in the preparation of the emulsion, enough lecithin to make 0.5 per cent. in the completed vaccine is thoroughly mixed with a little oil and is then ground with the bacterial material as is the lanolin. Lecithin has the disadvantage of making a foamy emulsion; this settles on standing, but it takes up air bubbles on very slight shaking.

Sperm oil has been tried in making the emulsion, on account of its being of the nature of a liquid wax.

We find that the preliminary grinding kills the bacteria; and tests are now being made to determine whether this grinding to a fine powder makes the bacterial material more rapidly absorbed. Possibly this preliminary grinding should be limited to merely breaking up the bacterial mass so it will mix with the lanolin.

We heat the final oil suspension to 53 C. for one hour on a water bath. Pfeiffer and Besseau[4] found that heating a saline suspended vaccine extracted the antigenic substances from the bacteria very rapidly and very thoroughly. Tests are now under way to determine whether this is the case in an oil suspended vaccine, and whether the heating is of any advantage.

ADMINISTRATION OF THE VACCINE

In our previous note we gave the method of administering the vaccine. We find a needle, No. 21, B. and S. gage, with a cannula three-fourths inch long entirely satisfactory.

In giving the lipovaccine, the possibility of fat embolism from accidentally getting some of the vaccine into a vein has been considered. Le Moignic and Pinoy[5] noted tachycardia in the mice in their early series; but they considered this to be due to the 1 per cent. of camphor they used in the vaccine. They did not notice any reaction of this kind in later injections with vaccines which contained no camphor.

Graham[6] says that fat embolism may be a frequent and often serious complication of such conditions as fractures, but that it seldom causes death. In experimental work, Graham found that a single dose of 0.8 c.c. of oil injected into the ear vein of rabbits gave only a slight passing dyspnea, or no evidence of discomfort.

Thus, it appears that the danger of fat embolism in giving the lipovaccines is slight; and this agrees with experience in the injection of mercurial oil (gray oil) and other oil preparations. However, our warning is very definite to make the injection subcutaneously, and carefully to avoid getting the vaccine into a vein. After the needle has been introduced, the plunger of the syringe should be drawn out slightly, to be certain that the needle is not in a vein.

THE DYSENTERY LIPOVACCINE

In our previous publications we have indicated as our reason for considering that a dysentery lipovaccine would have a special advantage over a dysentery saline vaccine, that the slow absorption would reduce the reaction; and we gave some results of vaccination of animals and men with such a vaccine. As the series is now broken up, and a much more comprehensive series is under way, we wish to record the final results of the first series.

The vaccine contained 2,500 million each of Shiga, Flexner and "Y" types in 1 c.c., the strains that Gibson[7] used in his vaccine being employed.

Three rabbits were injected with the vaccine, and showed the agglutinations given in Table 1.

TABLE 1.—AGGLUTINATIONS IN THE RABBIT

		Agglutination		
Rabbit	Dose	Shiga	Flexner	"Y"
16*	1 c.c.	1:100	1:800	1:400
17	1 c.c.	1:3,200	1:1,600	1:2,400
18	2 c.c.	1:100	1:400	1:1,600

*Rabbit 16 died two months after vaccination.

Two men were injected with the vaccine, and showed the agglutinations given in Table 2.

TABLE 2.—AGGLUTINATIONS IN MAN

		Agglutination*		
	Dose	Shiga	Flexner	"Y"
R.†	0.25 c.c.	1:200	1:200	1:37
St. J.	1 c.c.		None	

* The agglutinations of these men are reversed in the preliminary note.

† R passed from further observation.

Two and one-half months after vaccination, St. J.'s serum in dilution of 1:20 gave immediate cloudiness, and precipitation after two hours, with an extract of the Shiga type. His serum gave only a slight opalescence with extracts of the Flexner and "Y" types. Control serums remained clear.

Two and one-half months after vaccination, the serum of St. J. and of Rabbits 17 and 18 showed an opsonic index of from 0.26 to 0.82 for Shiga and Flexner, and an opsonic index of from 1.35 to 1.81 for "Y." In studying the smears made for the opsonic index, it was noted that there was marked bacteriolysis in all smears containing serum from the vaccinated animals and man. This may explain the low opsonic indexes; and this point is being studied in the new series.

Two and one-half months after vaccination, the serum of Rabbit 17 gave partial fixation of complement with all three types of the dysentery bacillus; the serum of Rabbit 18 and of St. J. showed no fixation of complement.

Two and one-half months after vaccination, Rabbit 18 received a dose of 2,700 million *B. dysenteriae* Shiga L intraperitoneally. The rabbit died during the night, apparently in about the same length of time as did the controls. The toxicity of this culture is such that 1,000 million intraperitoneally kill a rabbit in thirty-six hours.

For the new series of animals and men we have used a vaccine containing 3,000 million Shiga, 3,200 million "Y," and 2,200 million Flexner per cubic centimeter, using the strains that Gibson[7] used in his vaccine. Guinea-pigs stand up to 6 c.c. of this vaccine without ill effects; and we have vaccinated a series of men with 1 c.c. of this vaccine with no more local or general reaction than we get from a single dose of the regular triple typhoid vaccine in saline.

CONCLUSIONS

We find that the lipovaccines can be made on a large scale by growing the bacteria in Kolle flasks; taking off the growth with a vacuum scraper; freezing and drying in vacuo, and emulsifying in lanolin and oil by grinding in a ball mill, using glass bottles and steel balls.

The oils can be sterilized by steam at 15 pounds for fifteen minutes; by heating to 90 C. for ten hours on a water bath, or by mixing with potassium iodid.

We find that we can give men a dose of 3,000 million Shiga, 3,200 million "Y," and 2,200 million Flexner type of the dysentery bacillus in oil without marked local or general reaction. We find production of agglutinins, precipitins and bacteriolysins in the blood of vaccinated animals and men, and there is some evidence of complement fixation.

THE INFLUENCE OF FORCED DIURESIS IN EXPERIMENTAL POISONING WITH DIPHTHERIA TOXIN *

W. D. SANSUM, M.D.
CHICAGO

This records an effort to apply the principle of forced diuresis or histolavage to the treatment of experimental poisoning with diphtheria toxin. As certain of the bacterial poisons are known to be capable of excretion in considerable amounts by way of the urine, a great acceleration of diuresis might appear to be a more rational procedure in the case of certain infections than in the case of poisoning with heavy metals. Diphtheria toxin was selected because it is sufficiently stable to permit of standardization. The work is reported for the sake of completeness along with that on glaucoma, mercuric chlorid poisoning, etc., since it serves to amplify our knowledge of what may or may not be accomplished by salt and sugar diuresis in general.[1]

TECHNIC

The same general plan was followed as in the mercuric chlorid work.[2] The diphtheria toxin was a stable product 2 years old. The fatal dose was determined intravenously, but not with the same degree of precision as in the case of the mercuric chlorid, owing to the varying resistances found in the different animals. We found that 0.021 c.c. of the toxin per kilogram of body weight killed four out of five dogs in from three and one half to six days. One part of the toxin in 100 parts of 0.8 per cent. sodium chlorid solution was administered intravenously in each case as a single dose. When diuretic treatment was to follow, the toxin was administered with the first few cubic centimeters of the diuretic solution. Three diuretic solutions were used: (1) an alkaline hypertonic salt solution (sodium chlorid, 2.2 per cent., and sodium carbonate, 0.371 per cent.; (2) an 18 per cent. glucose solution, and (3) an 18 per cent. glucose solution having the salt content of Ringer's solution (sodium chlorid, 0.7 per cent., potassium chlorid, 0.03 per cent. and calcium chlorid, 0.025 per cent.)

* From the Otho S. A. Sprague Memorial Institute, Laboratory of Clinical Research, Rush Medical College.

[1] A fifth detailed report covering phases of work outlined in a preliminary communication (Woodyatt, R. T.; Sansum, W. D., and Wilder, R. M.: Prolonged and Accurately Timed Intravenous Injections of Sugar, The Journal A. M. A., Dec. 11, 1915, p. 2067).

[2] Sansum, W. D.: The Principles of Treatment in Mercuric Chlorid Poisoning, The Journal A. M. A., March 23, 1918, p. 824.

The diuretic solutions were administered as in the experiments described in previous publications. In the first series of four experiments we gave more than the predetermined fatal dose of diphtheria toxin in the hope of obtaining a decisive therapeutic result. These dogs received 0.030 c.c. of the diphtheria toxin per kilogram of body weight instead of the 0.021 c.c. The two controls (Dogs 6 and 7) lived three and five days, respectively. The first treated dog (Dog 8), weighing 10.80 kg., received 30 c.c. of the alkaline salt solution per kilogram hour for three hours, a total of 1,083 c.c., and passed during that time 963 c.c. of urine. There was also a marked catharsis, which accounts for the urinary output being less than the fluid intake. This dog lived three days. The second treated animal (Dog 9), weighing 5.11 kg., received 30 c.c. of the same alkaline salt solution per kilogram hour for four hours, and also sufficient water from the second machine to prevent dehydration. During the four hours this dog received 1,543 c.c. of fluid, 628 c.c. of the alkaline salt solution and 915 c.c. of water, and passed 827 c.c. of urine and numerous watery stools. This dog lived five days.

RESULTS OF EXPERIMENTS

No.	Wt. of Dog, Kg.	Total Dose of Diphtheria Toxin, C.c. per Kg.	Intravenous Therapy					Urine, C.c.	Duration of Life, Days
			Diuretic Solution	C.c. per Kg. Hour	Duration of Injection, Hrs.	Total Amt. Injected	Fluid Used to Preserve Water Balance		
1	11.25	0.021	....	....	.....	.....	......	.....	2½
2	8.64	0.021	....	....	.....	.....	......	.....	3½
3	12.28	0.021	....	....	.....	.....	......	.....	6
4	15.11	0.021	....	....	.....	.....	......	.....	6
5	14.28	0.021	....	....	.....	.....	......	.....	14
6	11.82	0.030	....	....	.....	.....	......	.....	4
7	10.91	0.030	....	....	.....	.....	......	.....	5
8*	10.80	0.030	Alkaline salt solution	30	3	1,083	0	963	3
9*	5.11	0.030	Alkaline salt solution	30	4	628	915 c.c. water	827	5
10	20.66	0.021	Glucose, 18%	30	3	1,810	300 c.c. water	2,717	2
11	16.25	0.021	Glucose, 18%, in Ringer's solution	30	3	1,470	478 c.c. water	1,355	Lived
12	15.00	0.021	Glucose, 18%, in Ringer's solution	30	3	1,258	86 c.c. Ringer's	1,056	4
13	17.84	0.021	Glucose, 18%, in Ringer's solution	30	3	1,628	143 c.c. Ringer's	1,410	4
14	21.55	0.021	Glucose, 18%, in Ringer's solution	30	2	1,432	475 c.c. Ringer's	1,070	4
15	11.25	0.021	Glucose, 18%, in Ringer's solution	30	2	640	0	695	4
16	10.57	0.021	Glucose, 18%, in Ringer's solution	30	3	963	0	810	5

* Marked catharsis.

We poisoned the remaining seven dogs in this series with the marginal fatal dose of diphtheria toxin, that is, 0.021 c.c. per kilogram. Dog 10, weighing 20 kg., received the 0.021 c.c. per kilogram with the first few cubic centimeters of an 18 per cent. glucose solution, which was given at the rate of 30 c.c. per kilogram per hour for three hours. During the three hours the dog received 1,810 c.c. of the glucose solution and 300 c.c. of water, and passed 2,717 c.c. of urine. This was the greatest diuresis of any in the series. The dog lived only two days, or less time than any other animal in the series. The treatment appeared to have done harm rather than good.

This phenomenon of shortening rather than prolonging life we had noted before in the mercuric chlorid series, and in searching for a possible cause considered the idea that it might be due to the wholesale washing out of urea, chlorids and other essential salts of the body. With the next group of six animals, we poisoned as before, and used an 18 per cent. glucose solution having the salt content of Ringer's solution, preserving the water balance by the addition of extra Ringer's solution when needed. Dog 11 made a complete recovery, but the next five animals (Dogs 12, 13, 14, 15 and 16) died in four, four, four, four and five days, respectively. We were inclined to believe that the dog which lived had an unusually high resistance for diphtheria toxin, since something similar had been observed in Control Dog 5, which lived fourteen days.

In these experiments, water was passed through dogs at the rate of 30 c.c. per kilogram of body weight per hour for three or four hours. The same procedure, if carried out in the case of a man weighing 70 kg., would imply the intravenous injection of 2,100 c.c. of fluid per hour for a total of 6,300, or 8,400 c.c. in three or four hours, nearly all of this passing promptly out by way of the kidneys and bowel.

CONCLUSIONS

The intravenous injection of an alkaline hypertonic salt solution, an 18 per cent. glucose solution or an 18 per cent. solution of glucose in Ringer's solution failed to prolong the life of dogs poisoned with diphtheria toxin even when treatment was begun at the most favorable time, that is, simultaneously with the administration of the poison. These negative results discourage attempts to apply an identical procedure in clinical cases of diphtheria.

Mammary Cancer in Infants.—Dr. D. Z. Blanc reported at a recent meeting of the Spanish Gynecologic Society that in the last year he had encountered two cases of cancer of the mamma in young infants. One was a male child. The mamma had begun to enlarge soon after birth and at the age of 6 months the epithelioma had invaded the entire mamma and the glands in the axilla, but there was no ulceration and the growth was not adherent to the pectoralis muscle. Blanc excised the mamma, the pectoralis and the contents of the axilla. Three months later the child died from recurring hemoptysis. In the other case the cancer developed in the same way soon after birth and in a few months spread to the axilla and into the hypochondrium. It was inoperable when he first saw the child. Blanc stated that hemorrhage from the lungs, probably of cancerous origin, is not an uncommon complication after removal of mammary cancers in adults. Injecting a stain under pressure into the lymphatics of the mamma to ascertain the area of probable diffusion, he found the entire pleura colored by the stain, both the parietal and the diaphragmatic pleura. His communication is reproduced in the *Revista de Medicina y Cirugia Practicas*, 1917, **41**, 216, with the hypothesis he presents to explain these cancers in the new-born.

POINTS IN TECHNIC OF SEPARATING ANAEROBES *

JAMES L. STODDARD, M.D. (Boston)
Captain, M. R. C., U. S. Army
FRANCE

It is the almost universal experience of careful workers with anaerobic bacteria that difficulties are numerous in the sure isolation of a single strain from a mixed culture. The following seem to be the main sources of difficulty, with means of correction:

(*a*) The direct plating of exudate presents great difficulties on account of the cohesion of the material. A preliminary anaerobic culture in bouillon results in a fairly even suspension, some separation, and a medium that can easily be diluted. Plating from a culture in chopped meat medium or milk, or from surface cultures makes an even suspension more difficult.

(*b*) There is frequent tendency of organisms, especially when encapsulated, to stick together to a certain extent. Two different bacilli which are still adherent after the plating is completed may grow and form what appears to be a single colony. If the bacilli are very similar morphologically, deception is easy.

The ordinary method of making successive dilutions in agar is not reliable as a method of separation. The thick consistency of the medium prevents the bacteria from being greatly affected by shaking or stirring. Attempts at thorough mixing aerate the agar and make it more difficult to obtain anaerobiosis.

Grinding the culture between glass slides destroys many organisms, and when dilutions are made the bacteria may again adhere. It seems better to make the separation in the dilution from which the planting is to be done.

Shaking the culture, or a dilution in salt solution is more effective, but is not alone sufficient for many cases. Shaking with glass beads is better. A method, however, which has been found to be most effective consists in shaking the culture in salt solution in a corked test tube containing about ½ inch of coarse sand. Sea-sand is washed by being repeatedly placed in a basin, stirred, and decanted as rapidly as possible so that only the coarse grains settling very rapidly are left. Organisms, growing in bouillon in auto-agglutination, with clumps absolutely unaffected by ordinary shaking, even when long continued, could thus be broken up.

A number of experiments were tried with a strongly auto-agglutinable bacillus to see the effects of the addition of various substances to the salt solution on the adhesiveness of the bacilli. Alcohol, soap, sodium carbonate, hydrochloric acid, acetic acid and tannic acid were tried in several dilutions. The acids appeared to hinder separation; tannic acid seemed actually to cause adhesions. Dilute soap or sodium carbonate had a slight but definite tendency to help the separation.

For ordinary purposes, physiologic sodium chlorid solution seems sufficient.

After a moderately slight dilution of the bouillon culture is thoroughly shaken in a sand tube, a further dilution is made into a second sand tube, which is thoroughly shaken, and so on.

It was found that the aeration produced by shaking had no effect if the plating was done within a few minutes afterward.

(*c*) The difficulty of fishing deep colonies makes surface sowing advisable.

(*d*) Moisture on the plate results in colonies running together. This is especially bothersome when the plates are made anaerobic by the hydrogen and palladium sponge method. For this reason it seems better to either (1) make cultures on the surface of slants in test tubes, the cotton preventing the entrance of the water from the hydrogen and oxygen; to (2) put some water-absorbing substance in the anaerobic jar; or to (3) use the pyro-soda method. It is, of course, important to have the medium of the right degree of moisture to start with.

(*e*) One of the most interesting sources of difficulty is due to the tendency of numerous anaerobic organisms to produce spores. If a spore lies dormant on the medium so that it is included in a colony that grows over it, it may be fished when the colony is picked off, and grow later in the subculture. Or it may start to grow later than the vegetative bacilli, and the colony formed by it be so small at the time of fishing that even if it is included in a larger one, it will not be noticed.

The remedy for this difficulty is:

1. To have a most favorable medium for the bacteria, so that spores will germinate to as high a percentage as possible and as quickly as possible.
2. To have good anaerobiosis to favor growth of spores.
3. To allow time for the spores to produce noticeable colonies.
4. To pick off the surface of colonies without touching the agar. This is easier, the more luxuriant the growth.

It follows that the best portion to touch is where the colony is definitely heaped up or fairly thick, but at some distance from the center, in order to get a recent growth. A point half way from the center to the edge usually satisfies these conditions sufficiently well.

The matter of a favorable medium is important. Ordinary agar or sugar agar, or even agar made with tryptic broth is not as good as egg mediums. Extremely good results are obtained by the egg medium of Stitt (from 10 to 15 c.c. of bouillon to each egg, beaten, tubed and inspissated), with the following modifications. The bouillon used is made by adding to beef infusion broth an equal volume of either meat or casein digested by trypsin or pancreatic extract and filtered.[1] One per cent. glucose is added, and the reaction made slightly alkaline to litmus. This medium is quickly and easily made, and the materials can always be obtained. Slants are made in fairly wide test tubes. To get a perfectly smooth surface, the egg-bouillon mixture is allowed to stand in the tubing funnel for at least one-half hour after beating, and after tubing brought up very slowly to 85 or 90 C. in the inspissator, thus getitng rid of small bubbles.

Good anaerobiosis can be obtained by the pyro-soda or the palladium sponge method. The most practical forms of these methods seem to be: (*a*) the Wright method for single test tubes[2]; (*b*) the Bullock jar for several tubes or plates at one time, and (*c*) McIntosh and Fildes palladium-asbestos tins and test tubes.[3]

---

* From U. S. Army Base Hospital No. 5.

[1] Cole, S. W.: Lancet, London, 1916, **2**, 9.

[2] Mallory and Wright: Pathological Technique, Ed. 6, p. 128.

[3] McIntosh, J., and Fildes, P.: Lancet, London, 1916, **1**, 768; Compt. rend Soc. de Biol., 1916, **29**, 293.

The pyro-soda method for plates, as applied by several devices, is less convenient and takes more time. In any case the removal of air from the medium by heating to from 90 to 100 C. just before planting is advisable.

(*f*) The tendency for anaerobes to grow much more easily in symbiosis with aerobic organisms when anaerobiosis is not good makes it necessary to be careful in anaerobic methods.

(*g*) The motility of many anaerobes is an additional reason for care in reducing excessive moisture in the surface of the medium.

The main steps in the method are as follows:

1. An anaerobic culture is made in 1 per cent. glucose bouillon.
2. Successive dilutions are made in physiologic sodium chlorid solution and are shaken thoroughly in corked test tubes containing coarse sand.
3. From each dilution, successive streaks are made on the three or four slants of the modified egg medium of Stitt, made with tryptic broth, with 1 per cent. glucose.
4. They are grown two or three days under good anaerobiosis.
5. Fishing is done from the upper surface of colonies without touching the agar.

CASES SHOWING REMOTE RESULTS OF TESTICLE IMPLANTATION

G. FRANK LYDSTON, M.D.
CHICAGO

As I exhibited the first of the patients to a number of the members of the American Urological Association, and both patients at the meetings of the Chicago Urological Association in October and November last, there will be no difficulty in verifying the findings given below. As the cases already have been reported in detail, I will give at this time only a brief outline:

REPORT OF CASES

CASE 1.—A man, aged 30, had completely lost both testicles from infection following trauma. There were moderately marked feminine secondary sex characteristics; excessive and feminine distribution of fat was especially noticeable. There was complete impotence, with decided mental and physical inefficiency. Double scrotal implantation of entire testicles was performed, Aug. 1, 1915. The material was taken from a boy of 14, killed by a crushing injury. The testes were removed six hours after death, and kept on ice for thirty-three hours. Local progress of the case was uneventful. The patient returned home at the end of two weeks.

Three weeks later, he engaged successfully in coitus. His mental and physical efficiency rapidly improved and soon became normal. There was a gradual diminution of the flabby, feminine adipose tissue, with an increased masculinity of type. The condition at present, two years and a half after operation, is very satisfactory. The patient is athletic in appearance and indulges freely in athletic sports. He has lost 40 pounds of excess fat. His mental and physical efficiency and sexual power are normal.

The implanted testes still are in situ. The organs are somewhat smaller than those of the average boy of 14, and quite firm. At the time of operation, a small nodule about the size of a grain of wheat was found at the extremity of the cord on each side. These nodules have grown considerably, and are now about as large as good-sized peas. From present indications, I feel justified in believing that the results of the implantation of testicles in this case will be permanent.

CASE 2.—A boy, at the age of 13, had suffered severely from a vaccination, probably with a mixed infection. Shortly after the vaccination, which, he stated, made him very ill, he developed orchitis in one testicle, probably from an infected embolus. Following the orchitis the testicle atrophied. Several weeks later, the opposite testicle became similarly involved and speedily atrophied. Coincidentally, the penis became distinctly smaller. Some months later, the patient was examined by several surgeons, who diagnosed retained testis on the left side and suggested operation. The patient subsequently, when 17 years of age, was referred to me. He was tall and healthy looking, with distinctly feminine secondary sexual characteristics. The pelvis, mons veneris and mammary glands were suggestive of a girl just entering on puberty. No beard was in evidence, and the complexion was distinctly of the "milk and blood" feminine type. There was a bare suggestion of hair on the pubis. The left testicle was represented by a small, hardly perceptible nodule about as large as a small pea just below the external inguinal ring. The right testis was soft, outlined with difficulty, and about the size and shape of a small lima bean. The penis was no larger than that of a well developed child of 5 or 6 years of age. The voice was that of the usual boy of 17. Psychically, the boy fortunately was a normal, manly fellow, although there were no signs of virility.

After about six months' treatment with faradism with some slight improvement, I suggested an implantation. Other advice was sought, and several surgeons—one supposedly an authority—suggested operation for retained testis, despite the feminine sexual characteristics, and local conditions that plainly showed the absurdity of such an operation. The patient passed from my observation and did not return until two years later, when I found that an operation had been performed on the left side, with the inevitable result that the remnant of testicle on that side had completely disappeared.

At the second examination, the condition in general was the same as it had been two years before, save that the secondary feminine sexual characteristics were more pronounced. There still had been no manifestations of virility. The pelvis was distinctly feminine, and the mons veneris was covered with a well pronounced cushion of fat and very sparsely supplied with small hairs, the arrangement of which was suggestive of that of a young girl approaching puberty. The beard still was lacking. Implantation of the testes again was suggested and consented to.

The operation, scrotal implantation, was performed, Oct. 27, 1916. The material used was taken from a healthy boy, aged 15, twenty-four hours after death from carbon monoxid poisoning. The glands were refrigerated thirty-two hours. The epididymides were not removed, and the testes were not decorticated. There was very little reaction and practically no elevation of temperature following the operation, but the patient was kept in bed for ten days.

Sixteen months after the implantation, the implanted testes still are well defined, the right gland being much larger than the left, and both being as large as those of the average lad of from 12 to 14. The consistency of both glands is softer and more nearly approximates the normal than have any other thus far implanted. The patient has gained weight and strength and is virile, as demonstrated by moderately frequent erections and the fact that he has cohabited thrice in succession on numerous occasions, with orgasm and emission. Penile development has greatly increased, and the pubic and scrotal hair also has increased and assumed a more masculine type. The lines of the patient's body have changed appreciably and become more masculine in conformation, the cushion of fat on the mons veneris, especially, being reduced in size. The patient's own atrophied right testicle has increased in size and firmness, and the epididymis—which could not be discerned at the time of the implantation—now can be plainly outlined. The voice is distinctly more masculine; the beard is heavier, and a growth of hair has appeared on the forearms. As in Case 1, I believe that the results in this case are likely to be permanent. It must be remembered that these two cases comprise four distinct and separate successful testicle implantations.

COMMENT

I not only feel that my published impressions of the value of the sex gland implantation — notably in the matter of increasing physical efficiency, and especially physiosexual efficiency — have been confirmed by further experience, but I also am convinced that, when technic and material are right and the recipient is properly selected, continuity of hormone production by the implanted gland for at least a prolonged period is certain. That permanently beneficial physiologic and therapeutic results are equally certain seems probable. Thus far I have observed no case in which the implanted tissue has completely or even practically disappeared, prior to from twelve to eighteen months. In brief, I am convinced that my method of sex gland implantation long since has been taken from the purely experimental field, and that it now stands on firm ground as a valuable therapeutic resource.

25 East Washington Street.

TOXICITY OF THE AMERICAN-MADE ARSPHENAMIN (SALVARSAN)

REPORT OF CASES

JAMES C. SARGENT, M.D.
MILWAUKEE

At the outbreak of the world war, the original German-made salvarsan practically ceased being marketed in America as well as in France and England. The demand for the preparation had already assumed massive proportions. The natural result of this unsupplied demand was the manufacture of similar, if not identical, products by various concerns. Diarsenol, arsenobenzol, arsenobenzol "Billon" and other preparations were soon marketed as its substitute. Recently a preparation has appeared under the trade name of "Salvarsan," (arsphenamin) ostensibly manufactured in this country under the direction of the Farbwerke-Hoechst Company and by the process employed in the manufacture of the old German-made salvarsan.

Taking advantage of the large syphilitic clinic at the Marquette University School of Medicine, I have been attempting to arrive at some conclusions as to the relative therapeutic value and toxicity of these different preparations. A paper outlining this work is in the writing.

Recently the dispensary has been able to obtain some of the new arsphenamin now being made in New York by representatives of the Farbwerke-Hoechst Company of Germany. Having this new shipment at hand, I decided to give it a trial on five patients who had reported that day for an arsphenamin treatment. Three ampules, each containing 0.6 gm. of arsphenamin, were inspected and found not to be cracked. The contents of each was of the characteristic pale yellow color. The total of these ampules was dissolved in 225 c.c. of sterile water which had been distilled less than two hours before. After the arsphenamin was entirely dissolved, the solution was alkalized by the addition of a sufficient quantity of 15 per cent. sodium hydroxid to form and redissolve the precipitate. It might be said that this technic, together with that of the injection of the solution, was identical with that used in the administration of some 200 doses of salvarsan given in the past six months.

REPORT OF CASES

Case 1.—A young woman, with a recently suppressed secondary syphilis, had received five salvarsan treatments at intervals of two and three weeks without notable reactions. She was given 50 c.c. of the prepared solution (0.4 gm. of salvarsan) in one of the arm veins. As she was leaving the building she became cyanotic and fainted. She soon regained consciousness and began vomiting severely. When I saw her about fifteen minutes later she was very pale, had a fast, thready pulse, was still vomiting and was in a violent chill in spite of blankets. After an hour's rest she was sent home in an ambulance. She subsequently reported that she continued nauseated and chilled for about twelve hours.

Case 2.—A young man, suffering from an active hereditary syphilis, had received one injection of salvarsan the week before. No reaction followed. He was given 50 c.c. of the prepared solution (0.4 gm. of salvarsan). He walked to an adjoining room and was forced to sit down because of a sudden dizziness. He became cyanotic, was nauseated, and hungered for air. His pulse rose above a hundred and was of little volume. After resting an hour, he was allowed to return home. He subsequently reported that he had a severe headache, was nauseated, and remained very chilly for four hours despite going to bed.

Case 3.—A small colored boy, with an active hereditary syphilis, had received one salvarsan treatment the week before without reaction. He was given 25 c.c. of the solution (0.2 gm. of salvarsan) and left the dispensary. His guardian subsequently reported that he appeared to have suffered no reaction.

As I was about to give the fourth injection, I was informed of the condition of Patients 1 and 2. Becoming alarmed, I tested a part of the remaining solution with dilute hydrochloric acid and found that the precipitate reformed on acidulation. Being satisfied that the solution was properly alkalized, I diluted it with freshly distilled and sterilized water so that 50 c.c. contained a fraction less than 0.3 gm. of salvarsan.

Case 4.—A middle aged man, suffering a late syphiloderm, had received an injection of salvarsan the week before without reaction. He was given 50 c.c. of the remaining solution (0.3 gm. of salvarsan). Arising from the table, he complained of dizziness and faintness; but after resting a half hour he decided to return home. He subsequently stated that he suffered only a slight headache for the following twelve hours.

Case 5.—A young man in the late primary stage of syphilis had received no previous treatment. The needle was introduced into the vein, and the solution allowed to run. After 30 c.c. (0.18 gm. salvarsan) had been injected, he began coughing, became cyanotic, and complained of air hunger. The injection was stopped. The pulse became rapid and thin. In spite of blankets he continued in a violent chill for thirty minutes. After an hour his color returned and he was allowed to go home. He subsequently reported that he remained chilly, nauseated and with a bad headache for the following four hours. This patient had had a preliminary cathartic.

COMMENT

Having been convinced that these five cases alone were sufficient to give a very definite idea of the toxicity of the new American-made salvarsan (arsphenamin), I have abandoned its use. Realizing the wide reputation previously enjoyed by the old German-made product and the stimulus which that reputation is certain to give to the sale of the new American-made salvarsan, I have been constrained to make an early report of these cases, hoping to save others from my uncomfortable experience.

END-RESULTS OF FRIEDMANN'S VACCINE

HARRY LEE BARNES, M.D.
Superintendent, State Sanatorium
WALLUM LAKE, R. I.

Friedmann's attempt to cure tuberculosis by inoculation of patients with large doses of living acid-fast bacilli must ever remain of interest to medical men. The temporary results from the vaccine in 120 of our patients treated in 1913 appeared in an earlier report.[1] Observers may honestly differ as to whether a remedy has been beneficial to living patients, but the fact of death and the value of the mortality rate in determining results cannot be successfully disputed. In the accompanying tables the Friedmann cure is subjected to the acid tests of time and the mortality rate.

TABLE 1.—RESULTS IN ONE HUNDRED AND TWENTY CASES TREATED WITH FRIEDMANN'S VACCINE IN 1913

From these tables it appears that the sanatorium cases in the bacillary group had 29.38 per cent. survivors against 26.58 per cent. Friedmann survivors, and in the nonbacillary group the sanatorium had 90.54 per cent. survivors against 89.7 per cent. Friedmann survivors. If patients discharged during 1912 are examined, we find three and one-half years afterward that both bacillary and nonbacillary groups taken together had 48.24 per cent. survivors against Friedmann's 48.33 per cent. survivors at the end of the same period. Another group of twenty-three ex-patients reported to us that they had received the Friedmann treatment during 1913, after leaving the sanatorium. Only seven, or 40.4 per cent. of the patients, were living, Jan. 1, 1917. The duration of life after taking the vaccine of the sixty-two patients reported dead in Table 1 is shown in Table 3.

Three	2	25	6	75	..	..	8
Four	2	40	3	60	..	..	5
Totals ...	57	47	62	52	1	1	120

All the Friedmann patients had had the benefit of sanatorium treatment for many months, thirty-five being arrested or quiescent when the vaccine was given, and eight being ex-patient employees of the sanatorium who asked for the vaccine more to insure against relapse than because they had active disease. The vaccine was further favored in the foregoing comparison in that its survivors had been away from the sanatorium nearly a year's shorter time than the sanatorium survivors of 1911, and consequently the Friedmann survivors should have had a lower mortality rate.

CONCLUSION

From all these considerations it appears certain that this vaccine had no beneficial effect on the patients.

Artichokes as Food.—In the *Scientific Monthly* (March, 1918), Prof. T. A. Cockerell of the University of Colorado writes of the so-called Jerusalem artichoke, or the girasole, as he prefers to call it, as a neglected article of food. This tuber is native to the American continent, one of the few contributions to the vegetables of the world. Though growing prolifically, without much labor in the cultivation, very little attention is given to it. It is known that it has produced as much as 20 tons to the acre, and is valuable as a food for hogs, which animals harvest the crop themselves. Its use for human food is perhaps even less well understood and it is even less eaten now than some years ago. Analysis of the tuber, however, show that it is of almost the same food value as the potato, though the carbohydrate content is different and is said to require further investigation. It may be eaten raw or cooked. In the latter form it may be used in soups, in salads sliced with egg, celery or endive, with French or maionaise dressing; sliced, boiled or steamed tubers may be covered with milk, seasoned, covered with bread crumbs and then baked. Grated cheese may be added to this dish. Finally, they may be boiled, mashed, creamed, seasoned, rich white sauce added and eaten on toast. Professor Cockerell says that the cultivation of this plant, especially in small gardens, may add very considerably to the food resources of the country at a time when such increase is more than desirable.

Military Medicine and Surgery

A NEW ADAPTATION OF THE FACE MASK IN CONTROL OF CONTAGIOUS DISEASE

JOSEPH A. CAPPS, M.D. (Chicago)
Major, M. R. C., U. S. Army
CAMP GRANT, ROCKFORD, ILL.

One of the most troublesome problems confronting the medical staff of the base hospitals in camps is the prevention of cross infections.

A mistaken diagnosis in the examining room may place measles in a scarlet fever ward, or meningitis in a clean diagnostic ward. These mistakes are partially remedied by sending all doubtful patients to an observation ward, where they may be differentiated at leisure.

The development of a secondary infection as a result of an exposure some time previous to entrance into the hospital is unavoidable.

On the other hand, the contraction of a secondary infection directly from another individual in the same ward demands the most serious effort in the way of prevention. When a case of scarlet fever breaks out in a measles ward, the ward must be placed in quarantine for a week. By the end of the week another case may develop and require another week of quarantine. This may go on indefinitely so that the ward is barred from either receiving or discharging patients.

Most contagious diseases, such as measles, German measles, scarlet fever, pertussis, meningitis and diphtheria, are transmitted from one person to another by means of the secretions of the nose and mouth. Coughing, sneezing and talking convey the bacteria-laden droplets of mucus through the air.

The cubicle system, now used extensively in the Army hospitals, and consisting of sheets suspended on wire between the beds, restricts the dissemination of droplets so long as the patients remain in bed.

In addition to this system we have carried out from the beginning, at the Camp Grant base hospital, the practice of requiring physicians, nurses and ward men to wear gowns and gauze face masks. In this we have followed as closely as possible the methods employed at the Durand Hospital in Chicago. Weaver,[1] in a recent report, shows the efficacy of the mask at the Durand Hospital in protecting the physicians and nurses from contracting contagious diseases and from becoming carriers of meningococci and diphtheria bacilli. We can also attest to the remarkable protection of the mask at Camp Grant, for during the first five months not one nurse or physician contracted the disease of the patients with whom he or she was working. With all these measures, however, we were unable to prevent the spread of cross infection from patient to patient, since we have no facilities for effectively separating patients in a ward once exposed to a fresh contagious disease. The cubicle segregates the bed patients, but it is almost impossible to confine convalescent soldiers day and night to bed; furthermore, it is not possible to furnish the necessary service in nursing, bathing and feeding to render such segregation effective. The patients use a common wash room and latrine, and hence the opportunity of transmission is unlimited.

The quarantine of several measles wards at a time by successive outbreaks of scarlet fever created at Camp Grant, last winter, an acute situation. To relieve this situation we carried out an experiment, the description of which is my purpose in this preliminary paper.

MASKING THE PATIENT

The face mask has proved an undoubted success in protecting physicians and nurses from contagion. It seems reasonable that patients by wearing the mask should receive similar protection from either primary contagion, or if already ill with one infection, from a second contagion.

The experiment of masking the patients was first tried in a measles ward in which six successive cases of scarlet fever had developed at intervals of several days. After the introduction of this method, one more case of scarlet fever broke out in five days, but none subsequently. The system has since been tried in other wards with excellent results. In general wards exposed to scarlet fever the masks are worn by all patients for one week after the last exposure.

The essential principle of the method is that patients out of bed and out of the cubicle must never be unmasked, except when alone in the wash room. In order to make it effective a number of precautions are necessary. The following rules are posted in each ward and latrine:

RULES FOR CONTAGIOUS WARDS

1. A face mask must be worn continuously by all patients when out of cubicle.
2. In the latrine the mask may be removed only by permission and under the direct supervision of ward nurse.
3. Wash basins and bath tub are not to be used. For washing face and brushing teeth use running water over sink. Shower may be used under supervision. Use only liquid soap from container.
4. Only one patient will be allowed in the wash room at one time. Remove mask on entering and replace before leaving wash room.
5. Masks may be removed when patients are in bed.
6. Sheets between beds are not to be drawn back.
7. No smoking allowed.
8. Corps men, nurses and surgeons should wear masks and gowns when on duty in the ward. A guard should be on duty continually near the wash room.
9. All eating utensils should be sterilized after each meal.

MASKING PATIENTS IN THE AMBULANCE

Many patients in the hospital break out with a fresh contagious disease, the incubation period of which corresponds to the length of time they have been in the hospital. This circumstance strongly suggests that the disease was contracted on the date of admission. As patients with different infections frequently come to the hospital together in the same ambulance, the chance of cross infections is obvious. Attempts to avoid this danger by grouping cases affected with the same disease have been futile, because many are sent to the hospital at the beginning of fever or eruption and are not yet diagnosed. Further exposure to contagion takes place in the admission room, where patients are often crowded together awaiting examination.

To guard against this danger we have made it a rule that *every patient before entering the ambulance shall put on a face mask and continue to wear it until he*

---

[1] Weaver, G. H.: The Value of the Face Mask and Other Measures, The Journal A. M. A., Jan. 12, 1918, p. 76.

reaches his bed in the ward. This applies to all patients, whether they have any communicable disease or not.

It is too early to say to what extent this masking of patients in the ambulance has prevented cross infections, but we believe it has lessened the number materially.

AN ANALYSIS OF GOVERNMENT CARDIOVASCULAR EXAMINATIONS

AS CONDUCTED AT THE BASE HOSPITAL, CAMP HANCOCK, AUGUSTA, GA.

S. CALVIN SMITH, M.D. (Philadelphia)
Captain, M. R. C., U. S. Army
CAMP CUSTER, BATTLE CREEK, MICH.

These statistics have been compiled from the cardiovascular examinations of members of the Twenty-Eighth Division, N. G., recently completed. The total strength of the command approximated 35,000 men, of which number 1.11 per cent. were recommended for discharge, which recommendations form the basis of this analysis. While absolute statistics are of course not available, owing to the constantly changing personnel of the division, sufficient data from the cardiac examinations are available to form a figure basis for this report.

Familiar methods of physical examination were employed, plus the instrumental aid of the stethoscope, sphygmomanometer and polygraph. It is to be regretted that electrocardiography was not available, especially for the information which it would have afforded in differentiating the tachycardias, which may have been due to vagal or sympathetic nerve influence and hence extracardiac in origin, or which may have arisen from irritable or degenerative foci within the auricular or ventricular muscle. Further, the written record obtained from electrocardiography in borderline or in doubtful cases would be of profound statistical importance for future heart recruiting standards, when considered in connection with the subsequent sick reports of such men who are now accepted for service.

THE RECORDING OF EXAMINATIONS

A blank, the form of which is given herewith, was filled out for each man examined. The individual records were made available for future reference by cross-indexing the serial number under the headings "Patient's Index" and "Diagnosis Index." In order to facilitate the work of the clerk who recorded the findings as called off by the examining physician, certain standard descriptive words were printed on the blank that required only an underscoring stroke of the pen to record. The form is self-explanatory.

BASIS FOR REJECTIONS

The principles of interpretation of cardiac disease, as laid down in Circular 21, Surgeon-General's Office, July 14, 1917, were followed so far as any set of rules could govern the individual case being considered. Further than this, visible pulsations which were not due to emotional disturbance, accelerated pulse rates not attributable to the same cause, maximum cardiac impulses displaced downward or to the left, and any changes in rate, rhythm or volume of the pulse, were all accorded more significance than were the detections of cardiac murmurs, many of which disappeared on recumbency or following exercise. This most unconventional disappearance of physiologic or functional murmurs following exercise was attributed to a decreased tonicity of a strong heart when at rest; exercise increased the tonicity, the relaxed valve leaflets came again into apposition, and the murmur consequently disappeared. Full significance was of course accorded to a murmur which persisted at a given area and which was accompanied by accentuations of other sounds, provided it was transmitted along the usual classical lines for a given murmur, or accompanied by the characteristic thrills, by increased transverse diameters of given chambers of the heart, or by other frank evidences of cardiac disease.

In Care of Cardiovascular Diseases.

The exercise test of hopping 100 times on one foot yielded most valuable information, when taken in connection with other physical signs; it frequently elicited testimony of cardiac hypertrophy and myocardial affections which it would have been difficult to obtain without its use. In those hearts which were within the government limits of acceptance and apparently normal, exaggerated pulse rate of perhaps 130, which followed immediately after exercise would gradually decrease in rate in successive five second counts and would approximate 115 within fifteen seconds thereafter, being within twenty or twenty-five beats of normal when the first minute had elapsed; at the end of two minutes, pulse and respiratory rate were quite normal for the individual. But in those patients who presented other corroborative evidence of heart affections, the exercise test caused both pulse and respiratory rate to remain abnormally high at the end of two minutes. Had it not been for the exercise test developing a pulse deficit in three young men who apparently enjoyed excellent health, auricular fibrillation would not have been first recognized, to be subsequently proved by polygraphic studies.

Blood pressure estimates had a distinct value in determining rejection in early cases of aortic regurgitation. I chose to designate as "early" aortic regurgitant cases those patients who complained of precordial distress, who presented exaggerated breathing following sustained physical effort, who had a basal diastolic murmur indifferently transmitted along the right border of the heart, whose arteries were but slightly infiltrated, whose pulse, although quick, was not of the collapsing character described by Dominic Corrigan. Such early cases had not progressed to the degree of peripheral vascular relaxation which results in the Quincke capillary pulse, although it was interesting to note that dermographia was quite constantly present; the much sought for "pistol shot femoral" was not to be auscultated, nor was there clinical evidence of pronounced left ventricular preponderance. In such doubtful instances of aortic valvular disease, a comparison of the brachial and femoral systolic pressures, estimated when the patient was recumbent, showed a femoral increase of from 40 to 120 mm. of mercury, thus determining the rejection of the patient as physically disqualified for the service. The diastolic estimate was disproportionately low.

CAUSES FOR REJECTION

Comment on Table 1 might confine itself to the large percentage of mitral lesions found (66.58) and to the relatively small percentage (0.91) of aortic lesions detected. That these lesions were not incurred in the service is evidenced by the absence of any history of illness since being mustered in, thus establishing that the valvular defect existed prior to enlistment. *Nor do I incline to the view that the intensive training of Army life had magnified a previously insignificant valvular defect; there were no histories of a gradual "limitation in the field of cardiac response" which would make this point of view tenable.* Any one of several hypotheses may be held as to why these mitral lesions were not detected at the time of enlistment; when one considers the rapidity with which physical examination of recruits must be conducted, amid noisy surroundings and the shuffling of feet, with scant time for differential study and no time for a *sifting* of previous history, there is little justice in criticising the recruiting physician. Then, too, this official is naturally skeptical of the thrill, of the sharp apical "slap," of the accented mitral first sound and of the scarcely perceptible murmur of mitral stenosis; for he knows from long observation that any or all of these physical signs may be counterfeited by the overacting heart of excitement or of hysteria in the young. *Such patients may require rest in bed and comfortable familiarity with their surroundings before a definite diagnosis is reached;* at the base hospital at Augusta it was not unusual to supplement the appraisal of cardiac values in excitable youths by examining them when they were asleep and hence not susceptible to emotional disturbances.

TABLE 2.—PREVIOUS DISEASES

	Per Cent.
Abscesses	.15
Abscessed teeth	11.93
Angina pectoris	.30
Appendicitis	.46
"Bronchitis"	.15
Chickenpox	5.50
Chorea	.78
Digestive disturbances	.78
Diphtheria	9.75
Goiter	.15
Gonorrhea	10.53
Influenza	.30
Malaria	1.50
Measles	52.60
Meningitis	30.89
Mumps	1.68
Neuritis	1.83
"Pleurisy"	1.83
Pneumonia	13.60
"Quinsy"	1.68
"Rheumatism"	22.32
Scarlet fever	15.00
Smallpox	.30
Syphilis	1.33
Tonsillitis	35.93
Tuberculous glands	.15
Typhoid fever	11.62
Whooping cough	6.73

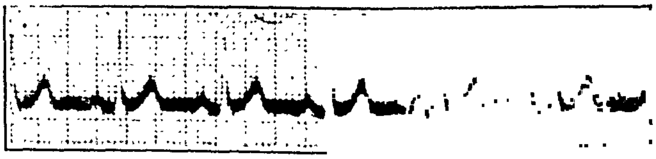
The relatively small percentage of aortic lesions that were found might be explained by the fact that aortic valvular involvements are usually rapidly progressive in developing to a degree at which they are accompanied by strong corroborative testimony of cardiac disease, and the recruit, as a consequence, is frankly sick at heart when he presents himself for enlistment and is promptly rejected.

CLINICAL COMPILATION

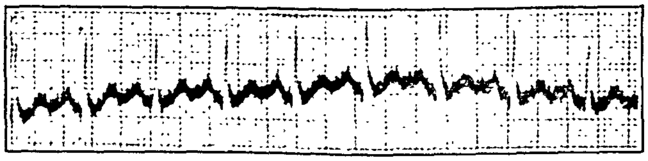
The average age of those examined was 23.59 years. Civil occupation was irrelevant as a causative factor in the conditions detected. Among military occupations, the Army cook seemed rather fated for dismissal from the service on account of heart disease. I was inclined to believe that these men chose cooking as a comparatively light occupation on account of being vaguely conscious that they could not "stand up" under the regular soldier's intensive gymnastics, drills and marches — a physical circumstance no doubt due to their as yet unsuspected cardiac lesions. Each patient was carefully questioned as to previous diseases; only one presented a history suggestive of circulatory failure. Precordial pain was surprisingly constant in the history of those who were subsequently rejected, being especially complained of as following continued exercise. Pain would thus seem to be a symptom of early cardiac disease, and should not be passed over without a thorough search for a heart lesion. Tenderness was present in less than 10 per cent. of those subsequently rejected, and when found was usually along the left border of the heart, being elicited by moderately heavy percussion.

EXPERIMENTAL STUDY OF THE "EXERCISE TEST" PRESCRIBED BY THE UNITED STATES GOVERNMENT FOR THE GUIDANCE OF SPECIAL CARDIOVASCULAR EXAMINERS

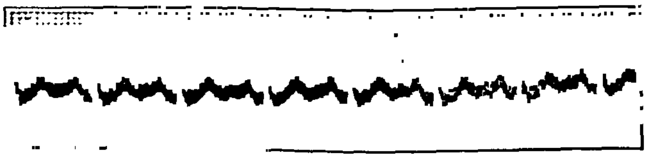
"The examination should include hopping 100 times on one foot, noting tachycardia and unusual dyspnea; after two minutes neither should be marked."



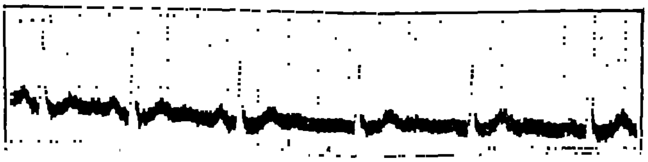
Electrocardiogram from an apparently normal heart before "hopping 100 times on one foot"; ventricular rate, 75; respiratory rate, 16 (Lead II, in this and following figures).



Curve from same heart immediately following 100 hops: ventricular rate, 120; respiratory, 30.



One minute later: ventricular rate, 105.



Two minutes later: ventricular rate, 75; respiratory, 16; both fallen to normal.

The streptococcic group of diseases — tonsillitis, "rheumatism," "quinsy" and abscessed teeth — in Table 2 hold their usual high percentage place as provocative factors in subsequent endocardial change. No credence is to be given to the small venereal percentages herein recorded; Army regulations inflict such penalties on the soldier who is so unfortunate as to develop a specific urethritis or an initial lesion that the man in the ranks, rather than forfeit pay and a curtailment of his personal liberties, may naturally be expected to deny venereal infection either past, present or future.

TABLE 3.—DISEASES OF CHILDHOOD

		Per Cent.
Measles		52.60
Chickenpox	5.50	
Diphtheria	9.79	
Scarlet fever	15.00	
Whooping cough	6.73	
Total all other diseases of childhood		37.02

Measles, in these figures, assumes a percentage importance far in excess of all the other acute, infectious, contagious diseases of childhood combined. The percentages are given in Table 3.

It would be reading entirely too much into these figures to assume from them that measles plays an important etiologic part in the endocardial changes of later life; it is, however, quite permissible to call attention to the earlier incidence of measles in over 52 per cent. of the patients later referred for evidences of cardiac disease. That this historically "harmless" disease of childhood may be a precursor of eventual heart damage suggests itself in a plausible light when one reflects that the complications and sequelae of measles, such as middle ear involvements, pulmonic invasions and chronic catarrhal conditions of the upper respiratory tract, are frequently suppurative in character and hence as fully capable of affecting the heart as are other septic processes within the economy. It remains for the pediatrician and for the family physician to determine, by frequent heart examinations during the course of and at stated periodic intervals subsequent to measles, whether or not a distant relation between measles and endocarditis, as cause and effect, shall find its way into our literature.

CLINICAL AVERAGES

I was struck by the large percentage (26.91) of thyroid enlargements in those who were examined for heart disease. This enlargement may have been a physiologic response of the thyroid gland to the demands that the hard and fast regulations of military life make on the nervous systems of those who have previously led a leisurely civilian existence; it may have been the result of frictional massage of the gland by the calisthenics and setting up exercises, which bring strongly into play the neck muscles of the soldier; or it may have been but an added touch of color to the clinical picture of heart disease. Whatever the cause, I am satisfied that it did not have the effect of increasing the pulse rate in the individual case, as one might at first thought suppose, from the averaged radial pulse rates, given in Table 4.

Eighty-eight per cent. of the men examined had pulse rates of 80 or more before exercise. The incidence of thyroid enlargement, mentioned in the preceding paragraph, had no bearing on the pulse rates when individually considered. Further, a studied effort was made to have the patient feel at ease during the examination; we do not believe that the pulse rate was increased by excitement or emotion. A third logical supposition might be that the men were overworked and "going stale" through overtraining, and that this was the responsible factor in the increased pulse rate, but on inspecting the records there is no appreciable difference between the pulse averages of those organizations which were examined when training first began and those organizations examined after four months of Army life. Antitobacco purists, on account of the prevalence of the habit in the Army, might read into these figures a pernicious activity of the fragrant leaf reflected in the pulse; there is nothing in the records either to refute or substantiate their statements. My conclusion then, from these figures and from further observations in the service is that "the average pulse rate of 72 per minute" is not the pulse rate to be found in active youths between 20 and 30 years of age; the radial rate may be expected to be ten or more beats higher than the classical average of 72.

TABLE 4.—AVERAGED RADIAL PULSE RATES

Rate before exercise	97.86
Rate immediately after	128.57
Rate two minutes after	92.69

The maximum apical impulse was measured from a definite and constant position on the chest wall, the midsternal line. This line was chosen in preference to the "midclavicular" or "nipple" line, both of which may be subject to either structural or to postural change. It was but the work of a second to draw the line from the base of the suprasternal notch to the ensiform cartilage, using the blued end of a celluloid centimeter rule for the purpose. The apical impulse was found to be normally located 7.5 cm. from the midsternal line in the fifth interspace. Mitral stenosis brought the apical impulse 2 or 2.5 cm. closer to the midsternal line; mitral insufficiency naturally threw it 2 cm. or more farther to the left of the accepted standard.

The transverse diameter of superficial cardiac dulness, which I had considered in civil practice as being normally between 9 and 11 cm., was distinctly increased in soldiers. While it was fully recognized that cardiac percussion is notoriously subject to many inaccuracies, it was employed for the reason that it was quite as dependable as any facility at hand for determining cardiac enlargement, in the absence of the accurate information afforded by orthodiography [illegible] group of cases, collectively considered, the diameter of the heart averaged slightly over 13 cm., percussed with the patient erect. Nor did the position of the apical impulse in mitral stenosis follow out [illegible] of downward displacement with the const[illegible] many authors teach us to expect; the apic[illegible] was in the sixth interspace in 48.98 per ce[illegible] mitral stenotic cases, and in the fifth interspace in the remaining 52.02 per cent.

STAINING FOR THE SPIROCHAETA PALLIDA IN SMEAR PREPARATIONS

LEON S. MEDALIA, M.D. (Boston)
Captain, M. R. C., U. S. Army; Chief of Laboratory, Base Hospital, Camp MacArthur
WACO, TEXAS

The difficulties encountered in making a diagnosis of a suspected primary lesion are well known. The use of a dark ground illuminator is sufficient evidence that the proper staining of the *Spirochaeta pallida* by the various methods described in standard books on pathologic technic is not an easy task.

Thus, Mallory and Wright[1] give not less than four methods of staining, besides Burri's india ink method. Every one of the methods referred to is fairly difficult, making it impossible for men with no special laboratory training to obtain proper results. In fact, in this laboratory, employing Wright's method as described by Mallory and Wright, we have tried time and again to stain smears of cases in which numerous spirochetes were found with the dark ground illuminator, but with no success. Of course, that does not condemn the method; but it at least shows that it does not work in the hands of every one.

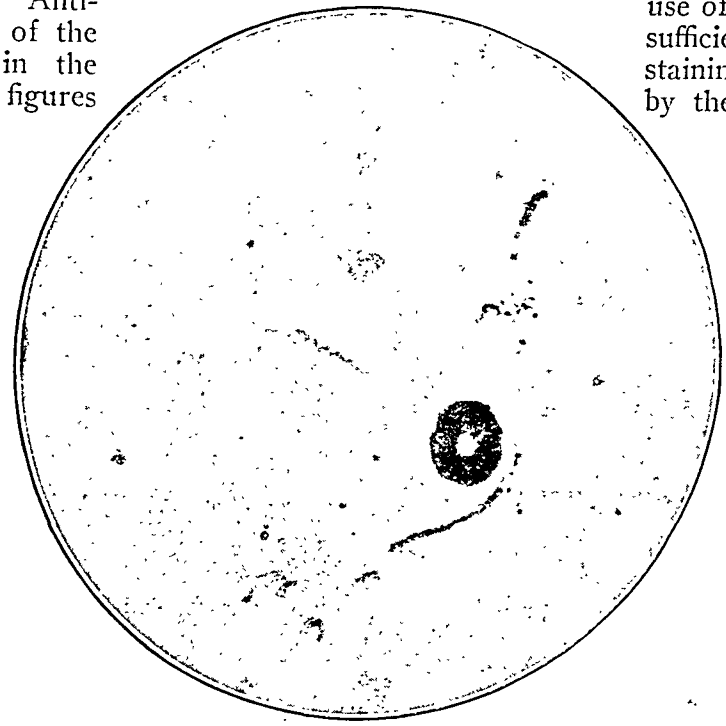


Fig. 1.—Smear made and stained by the simplified method. This smear and that given in Figure 2 were made from specimens examined with the dark field and reported negative, because no spirochetes could be found with the dark ground illuminator, after thorough search.

To obtain results with the dark ground illuminator, though easy at times, is as a rule a most difficult and time-consuming task. To spend a whole hour on an average case with the dark ground illuminator, searching for the spirochetes and then having to give up in disgust, is an experience familiar to any one who has used this method in a routine way. The desirability of having a specimen of such diagnostic import that will be a permanent specimen, one that can be filed away and referred to at any time in the future, similar to malaria specimens or tubercle bacillus smears, must be evident to any one. This point in itself would make the stained smears preferable to the dark field examination, provided the method of staining was sufficiently simple and would yield invariably good results. After trying out various modifications in staining, I ethod that fulfils these two conditions. It is easy of application, and with it I have found spirochetes in smears that were negative when examined from the wet specimen with the dark field illuminator.

---

[1] Mallory, F. B., and Wright, J. H.: Pathological Technique, Philadelphia, W. B. Saunders Company, 1915.

hod is as follows:

ace of the lesion is cleaned with a wad of sterile cotton, soaked in sterile saline solution, and all of the ed exudate is removed. The patient is then told to squeeze the lesion between the forefinger and the thumb until serous exudate appears. The appearance of the exudate may be hastened by scraping the deeper parts or the ragged edges of the lesion with a broken wooden applicator or with a stiff platinum wire. The exudate thus obtained from the deeper parts of the lesion should be mostly a serous exudate; real bleeding should be avoided. A good smear is one in which only an occasional red blood cell is found. The smears can be made on clean slides by placing a drop of deep exudate, obtained with a broken applicator, a sterile toothpick or a platinum loop, on one slide and spreading it out thinly with the other slide. The slides should be not pulled, but slid apart. The smears are then dried in the air, and stained with Wright's blood stain in the ordinary way, except that instead of plain distilled water to dilute the stain, 1 per cent. solution of sodium carbonate in distilled water is employed. The film is covered with Wright's blood stain, to fix the smear, a sufficient quantity being used, a little in excess of what is used in staining blood smears. At the end of from one to two minutes, to the staining fluid are added from 45 to 50 drops of 1 per cent. sodium carbonate solution in distilled water to a slide, or as much as the film will hold without running over. The diluted stain is allowed to remain on the film for fifteen or twenty minutes, and is gently steamed all the while with the flame of an alcohol lamp, as in the staining of sputum for tubercle bacilli by carbolfuchsin. The slide is then lightly washed with water, dried between filter paper, and examined with the oil immersion lens. The spirochetes appear intensely violet on a pale blue background, and are easily found.

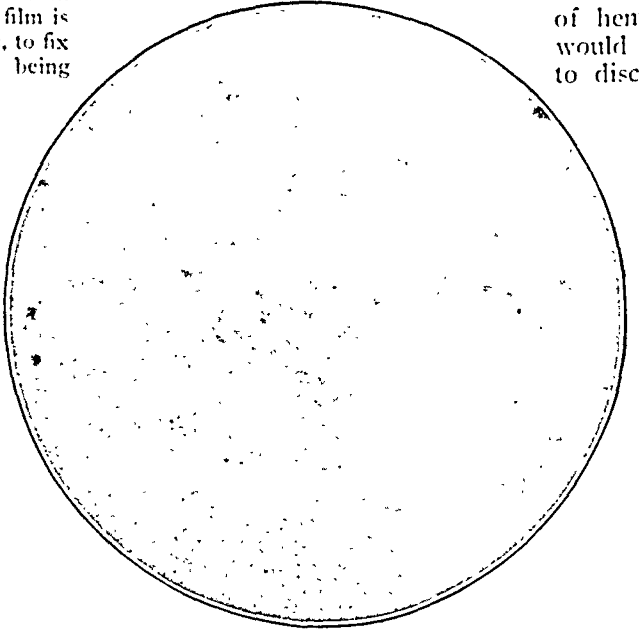

Fig. 2.—Another smear by the simplified method.

The advantage of this method is its simplicity; no special reagents or staining solutions are needed excepting 1 per cent. aqueous solution of sodium carbonate and Wright's blood stain. The results have certainly been most satisfactory.

Industrial Physicians and the Control of Cancer.—The American Society for the Control of Cancer in conducting propaganda has enlisted the aid of physicians and surgeons connected with large industrial plants throughout the country, who come in close contact with large bodies of men and women. An outline of a lecture on the control of cancer has been prepared by the council of the cancer society and the attention of these physicians has been called to it. Considerable interest has been manifested and many requests for the lectures have been received, as well as replies commending this form of educational work. In this connection the cancer commission of Harvard University has established a service for the free diagnosis of cancer which was inaugurated, October 1, 1917. It offers to the physicians of Massachusetts an opportunity for free examination of pathologic material removed at operation. This service was established on the suggestion of the American society.

PNEUMONIA AND EMPYEMA AT CAMP ZACHARY TAYLOR, KY.

A PRELIMINARY REPORT

WALTER W. HAMBURGER, M.D. (Chicago)
Major, M. R. C., U. S. Army

AND

LAWRENCE H. MAYERS, M.D. (Chicago)
Lieutenant, M. R. C., U. S. Army

CAMP ZACHARY TAYLOR, LOUISVILLE, KY.

Since the opening of the base hospital in September, 1917, there have been admitted to the medical service 274 pneumonia patients, 176 with the lobar and ninety-eight with the bronchopneumonia type. This series of cases has been most interesting and unusual, differing in several aspects from the well recognized picture of lobar pneumonia and bronchopneumonia. This variance in the disease picture has occurred in periodic waves due to the severity and character of the disease, the relation to measles, the incidence of empyema and other serious sequelae, the presence of hemolytic streptococci, etc. It would seem profitable, therefore, to discuss these cases chronologically.

The early cases, in September and October, about thirty in number, apparently conformed to the usual picture of lobar pneumonia, with sudden onset, chill, temperature, rusty sputum, localized areas of consolidation, etc. Although type determinations of sputum could not be made, because of inadequate laboratory facilities in the early days of the hospital, these pneumonias undoubtedly belonged to the more benign type of organisms (Type IV), as only one death occurred in the series. This patient, who apparently had a mild case, developed a severe pneumococcic meningitis three days after a typical crisis, and died within twenty-four hours. Because of insufficient equipment and nursing personnel at the base hospital at this early period of its organization, these patients were cared for in the wards of the Louisville City Hospital. To this hospital much credit is due for efficient medical and nursing care.

The first case definitely diagnosed bronchopneumonia occurred, October 22, ten days after the first measles admission. From then on, the number of cases of pneumonia following measles increased rapidly, paralleling closely the measles admissions, latterly decreasing pari passu. In contrast to the early benign lobar pneumonias, these bronchopneumonias following measles were most severe and fulminant. Developing usually during the third or fourth day of the rash, the pneumonic process was ushered in by an increase in temperature, respiratory rate, patchy areas of dulness, roughened bronchovesicular breathing, moist bubbling râles and, of particular interest, marked dyspnea and dusky cyanosis of the face. The latter two symptoms, interpreted as evidences of air hunger, increasing in severity with the progress of the pneumonitis, were most distressing and difficult to relieve. With fair degree of accuracy, one could often pick out the incipient pneumonias by noting the degree of cyanosis and blueness of the face, and by the same token could estimate the patient's chances of recovery.

From an epidemiologic standpoint, considerable interest attached to the time of the development of the pneumonia in relation to the period of hospitalization or discharge to quarters. Of a total of 102 cases of pneumonia following measles developing up to January 17, eighty-seven developed during the soldiers' stay in the hospital, while only fifteen were readmitted after discharge to quarters. In other words, the majority developed while in the hospital wards as close sequelae to the primary disease, either as contact or droplet infections from other patients, ward air or ward dust, or from the patient's own bacterial flora from mouth or nasopharynx, the minority developing after return to duty.[1]

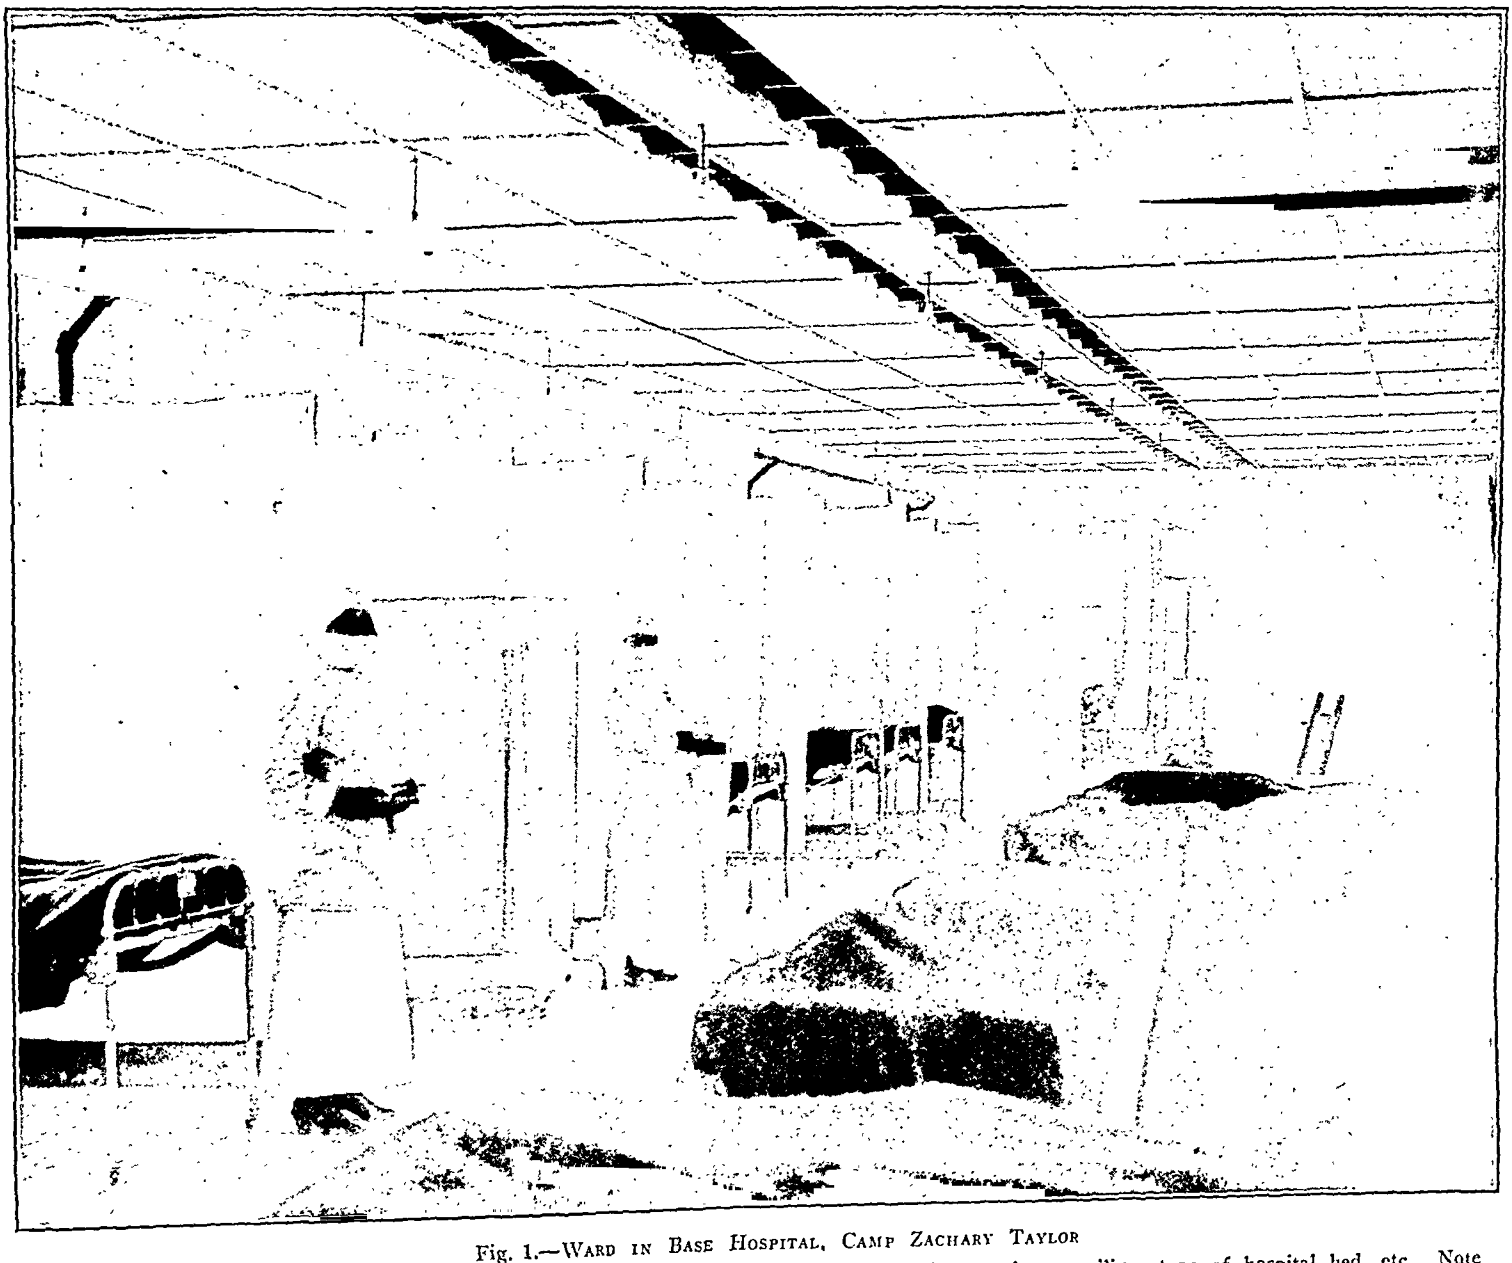

Fig. 1.—Ward in Base Hospital, Camp Zachary Taylor

This picture shows the cubicle method of isolation, method of heating and ventilating wards on ceiling, type of hospital bed, etc. Note face masks worn by nurses in attendance on cases of pneumonia.

At necropsy, the lungs of these patients contained scattered, small or large areas of bronchopneumonic consolidation, with often multiple peribronchial abscesses from which thick greenish gray pus could be expressed. Hemorrhagic and purulent tracheitis, bronchitis, bronchiolitis and bronchiectasis were usually present, while a markedly dilated right auricle served as evidence of antemortem cardiac failure.

About December 1, the fulminant atypical lobar pneumonias, later proved to be streptococcal in origin, began to appear and continued well past the middle of January. From the standpoint of the prodromes, these cases divide themselves into two classes: first, those starting insidiously with "sore throat," "cough," "grip," for a few days, progressing gradually until frank signs of consolidation could be elicited, and second, cases starting abruptly, severely, with sudden overwhelming prostration and collapse, profoundly toxic, progressing rapidly to death within three or four days, with symptoms so profound and acute as to suggest a general sepsis. These cases were most distressing. Because of the speed of development of the disease, and the evident urgency of the soldier's distress, little could be done to stay the progress of the disease, and one's utter helplessness in combating it was daily forced on us. Digitalis, caffein, venesection—nothing seemed to make the slightest impression.

---

[1] The establishment of cubicle isolation, in compliance with orders from the office of the Surgeon-General, by hanging sheets on wires strung through the wards between each bed, was of material benefit in preventing the spread of pneumonia (Fig. 1).

In both of these groups of cases, empyema developed in an extremely high percentage, eighty-six cases in 274 pneumonias, an incidence of 31.4 per cent. In the four week period from December 17 to January 15, the empyema "epidemic" reached its height. Of 109 pneumonias, fifty-two developed pus in the pleural cavity, an incidence of almost 50 per cent.! This rise in the empyema cases, reaching its height Christmas week (fifteen out of eighteen lobar pneumonias developing empyema), was in marked contrast to the week of January 15 (of twenty-six pneumonias, only four empyemas). These variations in the empyema curve were quite separate and distinct from the pneumonic curve per se, and were probably due to the virulence (selective action?) of the invading organisms (hemolytic streptococci).

This series of eighty-six empyemas differed in several striking respects from the metapneumonic and parapneumonic empyemas usually seen. Many patients came into the receiving ward from the regiments with chests full of pus. In other cases, within an hour or two of admission to the wards, quantities of pus could be readily demonstrated. In both, a history of illness not to exceed twenty-four hours was often obtained. The extremely rapid development of the empyemas, often well within twenty-four hours, was demonstrated repeatedly by fluoroscopic and roentgenographic examination.

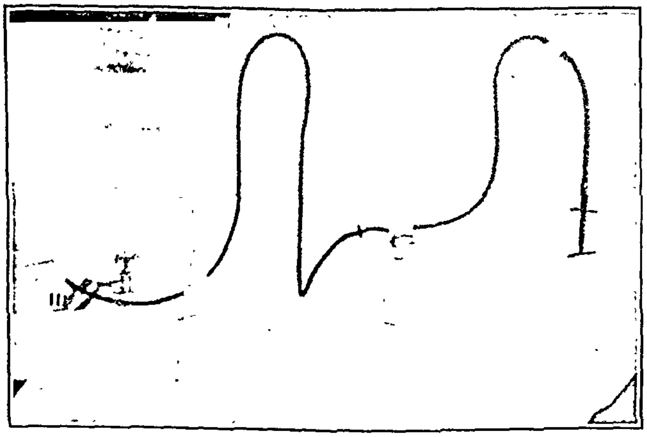

Fig. 2.—Brewer tube and attached water pump for continuous suction.

Physical signs were most misleading. Traube's space, displaced cardiac impulse, tubular breathing, and bronchophony giving little differential aid in doubtful cases. Dulness to flatness on percussion, particularly when associated with diminished breath sounds, were in most cases dependable. Intense loud tubular breathing, rasping in character, almost invariably meant fluid. This apparent paradox is probably explained by compression atelectasis, with ready transmission of bronchial sounds by the thick plural exudate.

Clinically, the severe prostration with flushed cheeks, hollow bright eyes, short grunting dyspnea, deep boring chest pain, and asymmetric chest excursion were most prominent. Later this severe pleural pain was relieved somewhat, owing probably to the separation of the inflamed surfaces by the developing exudate.

Many cases, diagnosed clinically massive lobar pneumonia, showed at necropsy widespread atelectasis with the lung compressed to half its normal size, but with little or no evidence of pneumonic consolidation. In these cases, purulent pericarditis was frequently associated, the pericardium containing a pint or more of thick, creamy pus.

Hemolytic streptococci were found in pure culture in a majority of the empyema fluids, fifty-two out of ninety-three examined, the remaining containing pneumococci or mixed organisms, or remaining sterile. The preponderance of streptococci was further emphasized by their presence in blood culture, pericardial pus, lung smears, and the heart's blood in these cases. Similar organisms were found widely distributed in various types of disease coming into the hospital at this time—almost universally in tonsil and throat smears, mastoid, middle ear and antrum pus, joints, abscesses, etc. The laboratory findings, together with complete absence of lung involvement in many instances, and the sudden overwhelming prostration and profound toxemia, with death in a few days, suggest that these so-called pneumonias are in fact true cases of streptococcic sepsis, with early localization in pleura and pericardium.[2]

Treatment has been disappointing. Of eighty-six patients with empyema, twenty have died, six have been discharged to duty, and sixty remain under treatment in the hospital. Rib resection has been ineffectual; no patient having this type of treatment left the hospital, while nine have died. Intercostal drainage with continuous suction from an attached water pump is being used at present with greatly improved results (Figs. 2 and 3). The routine of examination and handling of these patients at the present time is as follows:

1. Every patient showing bronchopneumonia and lobar pneumonia, severe sepsis, continued high temperature without demonstrable cause, severe continued dyspnea, particularly when accompanied by a sense of marked discomfort or pain on breathing, and a feeling of fulness or tightness in the chest shall be considered as having *potential* empyema, and shall be observed constantly with this possibility in view.

2. Each potential empyema patient shall be roentgenographed within forty-eight hours of admission, provided the patient's condition permits.

3. Each potential empyema patient shall be seen by the special empyema surgeon within forty-eight hours after admission, for consultation regarding exploratory thoracentesis.

4. A positive thoracentesis shall be followed immediately by the Potain treatment, as much fluid being withdrawn as is compatible with the patient's condition. A specimen of such fluid each time obtained shall be sent to the laboratory for examination.

5. In proved cases of empyema the patient shall be examined daily and roentgenographed, and tapped at least every third day. On the fluid's becoming opaque and of cream or purée consistency, the patient shall be transferred to the surgical service for continuous drainage with suction apparatus, unless ordered otherwise.

In explanation of the foregoing order, it should be emphasized that exploratory tapping and use of the

---

[2] Jochmann (*Streptokokkensepsis*, Lehrbuch der Infektionskrankheiten, p. 137) calls attention to the fact that a streptococcus sepsis may progress with the picture of a lobar pneumonia in which the pneumonic process may be either the source of the sepsis or develop secondarily from it; and further, that the pleura may be the seat of a primary streptococcus empyema, later serving as the source of a streptococcus sepsis.

Potain treatment is not without danger. There have been several instances of collapse following both procedures in the several hundred times they have been used, in one case sudden death, probably due to suddenly lowered blood pressure (pleural vagosympathetic reflex [Capps and Lewis]). A number of other patients, although showing no ill effects at the time, have within twenty-four hours become markedly worse, with extremely low blood pressures, rapid thready pulse, drenching perspiration, pale clammy skin, either the result of the withdrawal of too large amounts of fluid, or the releasing into the circulation of overwhelming quantities of toxic substances. Recently the use of 0.5 per cent. cocain solution, anesthetizing down to and including the pleura, not moving the point of the needle around after pleural puncture, withdrawing the pus through the same syringe, and only a relatively small amount the first time, particularly if the fluid is clear, have resulted in no further mishaps.

SUMMARY

1. The bronchopneumonias and lobar pneumonias occurring at Camp Zachary Taylor, Ky., during the winter of 1917-1918, were most atypical, differing in mode of onset, clinical characteristics, incidence of empyema, presence of hemolytic streptococci, etc., from the usual picture of pneumonia.

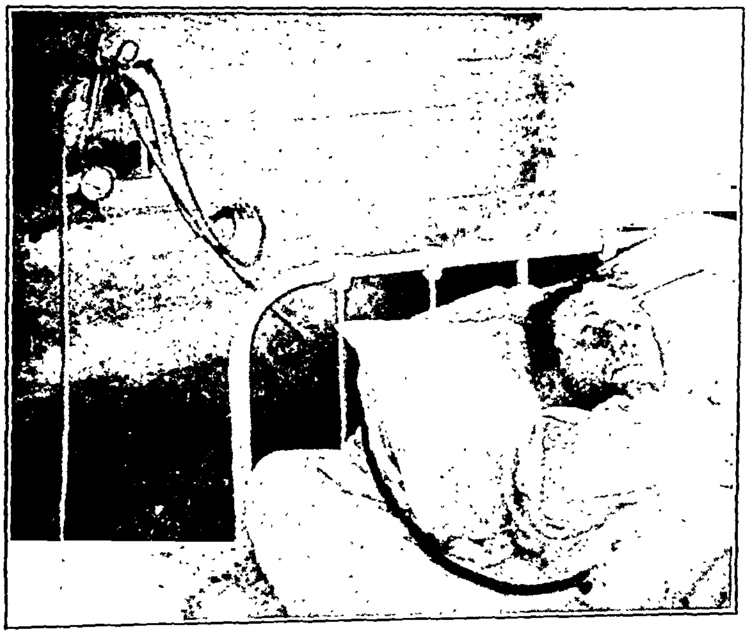

Fig. 3.—Apparatus for continuous chest drainage in place.

2. Many cases diagnosed clinically lobar pneumonia showed at necropsy no evidence of pneumonic consolidation, but contained large amounts (3 liters [quarts] and more) of empyema pus and atelectatic lung tissue. Such cases may be considered examples of primary suppurative pleuritis.

3. The severity and rapidity of the onset, course and termination of many cases, the overwhelming prostration and toxemia with death measured in hours, the presence of hemolytic streptococci in empyema pus, blood cultures, metastatic abscesses in joints, cellular tissues, pericardium, middle ear, mastoid, meninges and brain, and the inefficacy of treatment all lend strong support to the view that these cases are true examples of streptococcus sepsis.

4. The empyemas of this series are notable from the standpoint of their incidence (31.4 per cent.); their early development, often primary; their rapid development within twenty-four hours; the presence of hemolytic streptococci; their occurrence as part of a general sepsis (distinct from pneumonia); the difficulties of interpretation of physical signs; the advantages of roentgenographic examination, and the difficulties and indications of various forms of treatment.

5. The character of the empyema fluid gradually changes, becoming progressively more turbid and heavier. The greatest benefit from surgical interference is obtained by delaying operation until the fluid becomes opaque, greenish gray and of cream or purée consistency. Operations instituted earlier or later are of less benefit. The use of intercostal drainage with attached water pump for continuous suction has been superior to other forms of surgical treatment. This method imposes a minimum of surgical trauma; prevents the aspiration of foreign material (secondary infection) and collapse of the lung from pneumothorax; allows the pus to escape gradually; maintains negative intrapleural pressure, and shortens the patient's period of invalidism.

GUNSHOT WOUNDS OF THE KNEE JOINT

CASUALTY CLEARING STATION AND BASE HOSPITAL OBSERVATIONS ON EIGHTY-FIVE CONSECUTIVE INSTANCES, WITH A NEW METHOD OF DRAINING THE KNEE JOINT

KELLOGG SPEED, M.D. (Chicago)
FRANCE

In 1916, in the service of the British expeditionary forces, France, there was much discussion among the medical officers regarding the best method of active care of these serious injuries. On the whole, there was a tendency to collate the different treatments and to watch for final results. In the late part of the year, a course of action crystallized out of this chaos. During 1916 at the general hospitals, victims of battle casualties were frequently received fresh from the trenches, when only slight operative interference had taken place. This was especially true of gunshot wounds of the knee. A perusal of the tabulation made at that time to cover these patients now seems unsatisfactory, although any desired line of procedure in treatment was then possible for the relatively untouched wounds. Sepsis predominated. Mortality was high, and nearly one half of these cases went on to high amputation. Now, a more or less uniform method of first treatment is in vogue at casualty clearing stations, which are more numerous than before and better equipped for the demands of the delicate surgical technic required for this type of wound.

The subject of gunshot wounds of the knee is so large that it merits division. The general opinions here expressed are the result of careful tabulation and study. It is desirable to consider these casualties on the assumption that the wounded are handled surgically within a short time after their injury. The question of the drainage of septic knee joints alone is large, deserving deep study. It will be mentioned here only in relation to the treatment of some patients of this series, and to suggest a newer method.

Individual records of each patient coming into the service were made for my personal use, observations in many instances extending over several months. A tabulation of eighty-five consecutive patients was prepared according to the following outline, and the figures given are based on a study of the table.

OUTLINE FOR STUDY OF GUNSHOT WOUNDS OF KNEE JOINT

1. Type and location of wound related to a transverse line through patella:
    - (*a*) Was there exit and entrance?
    - (*b*) Was synovial surface alone involved?
    - (*c*) Was there fracture accompanying? Which bones?
    - (*d*) Was foreign body present? In joint? In bone?
    - (*e*) Was joint traversed by foreign body?
2. Type of first treatment:
    - (*a*) Where given? Field ambulance? Casualty clearing station? Base hospital?
    - (*b*) Was the joint opened by missile or by operation?
    - (*c*) Was the joint irrigated?
    - (*d*) Was joint "bipped"?
    - (*e*) Was foreign body removed? Or bone fragments?
    - (*f*) Was joint closed by sutures?
    - (*g*) Was joint left open?
    - (*h*) Was joint drained by foreign material, e. g., gauze, gutta percha, tube?
3. Were splint and extension used?
4. General data:
    - (*a*) Condition of patient on admission.
    - (*b*) Joint pain, swelling, redness, discharge (pus or synovial fluid).
    - (*c*) Temperature curve.
    - (*d*) Cultures made. Results.
    - (*e*) Was joint aspirated? Drained?
    - (*f*) Other secondary operations.
    - (*g*) Condition on discharge from hospital.
    - (*h*) Probable prognosis.

GENERAL PROCEDURE IN ROUEN DISTRICT

There are several important reports on this type of wound. The most interesting general collection of knee injuries was made by Barling[1] in the Rouen hospital district, from June to December, 1916. It is, of course, understood that any final record of these patients is impossible because wounds and a large part of their treatment occur in one country, while subsequent care and the final disposition of the patient take place in another, in scattered hospitals. Like every other man who studies these gunshot wounds, Barling discovered that the statistics clearly reveal a high proportion of patients whose wounds required early excision, removal of the damaged bone and any retained foreign body, joint irrigation, and closure by suture, and later followed a course of satisfactory healing which required no further surgical interference. The findings in 845 knee joints operated on in the Rouen district are presented in Table 1.

TABLE 1.—RESULTS OF EIGHT HUNDRED AND FORTY-FIVE OPERATIONS ON THE KNEE JOINT

Classification of Wounds	No. of Cases	Percentages
1. Total number cases of injury to knee operated on	845	....
2. With bone injury	438	....
3. Without bone injury	407	....
4. Wound excised and closed	322	....
5. Cases under (4) requiring further operation*	82	25.5
6. Wound excised and packed	336	....
7. Cases under (6) requiring further operation*	128	38.4
8. Excision of knee	42	....
9. Arthrectomy, partial or complete	15	....
10. Excisions or arthrectomies amputated	13	22.8
11. Deaths after excision or arthrectomy	13	22.8
12. Amputation without excision	151	....
13. Deaths under Class 12	49	32.4
14. Total amputations	164	19.4
15. Total mortality	72	8.5

* One hospital with a large number of cases was unable to separate the cases under items 4 and 6.

SUMMARY OF RESULTS IN EIGHTY-FIVE CASES

In our present series of eighty-five patients, the synovial lining of the joint was opened by the missile in every instance. There were two deaths. In both cases the patients suffered bone injuries at the knee, and one died from a gas infection of his arm, which was amputated, the knee apparently doing nicely. In reality, then, there was only one death caused by the knee injury, due to generalized sepsis, since no secondary operation was performed.

The synovial surface alone was involved in forty-two instances, in three of which, or 7 per cent., amputations were made. There were bone injuries accompanying forty-three knee wounds, in six of which, or 14 per cent., amputations were made. We might suppose, then, that a knee gunshot wound which causes simultaneous bone injury is twice as liable to go on to amputation as one without bone injury. Clinically, there seems to be a higher ratio. In twenty-five patients, foreign bodies were present in the joint, in eighteen patients they were present in the bone.

The amputations numbered nine, or approximately 10 per cent., though Barling figures 20 per cent. Six of these had complicating bone injury. The foreign body was removed in seven. The wounds of six of the nine patients were excised early at casualty clearing stations or field ambulances. One was excised late at the base and two were never operated on. In addition to these nine, there were three patients who may possibly have gone on to amputation later in England. There is no record of them after leaving the base hospital. They were under observation a long time and were finally sent away during a rush of the wounded needing beds.

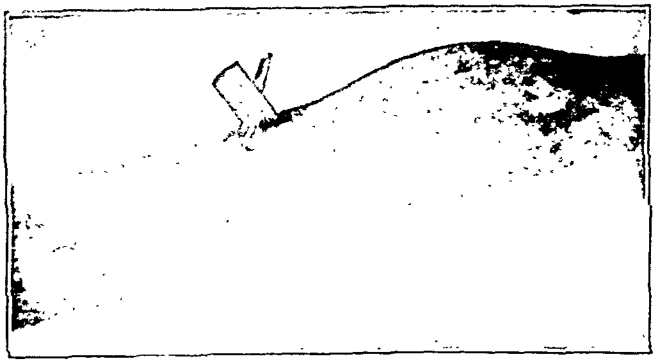

Fig. 1.—Drainage tube inserted in upper margin of subcrural pouch.

Looking at the figures from another standpoint, we find that sixty-six of the eighty-five patients suffered penetrating shots, with no wounds of exit. The results are as set forth in Table 2.

TABLE 2.—RESULTS OF TREATMENT OF SIXTY-SIX PATIENTS

	No. Patients	Percentages
Death	1	....
Loss of limb	8	12
Fair result (meaning stiff knee or markedly impaired function, but the leg saved)	11	16.5
Good result (a movable knee promising a high degree of function)	27	40
Excellent result (with hope of nearly normal function)	19	29

The through and through perforating shots (wounds of exit and entrance) were found in nineteen instances. The results were as follows: one case of death from gas infection of the arm; one case of loss of limb or 5 per cent.; two, or 10 per cent., in which the results were fair; ten, or 50 per cent., in which the results were good, and five, or 25 per cent., in which the results were excellent.

---

[1] Barling, H. G.: Brit. Med. Jour., 1917, 2, 277.

We might believe, then, that the result depends not so much on whether a wound is penetrating or through and through as it does on other factors, namely, early surgical excision and the presence or absence of concomitant bone injury.

Taking the early treatment into consideration, we find that in eighty-five instances, sixty-five were treated as early as possible by wound excision and joint closure, leading to fifty-five fair to excellent results. Of the sixty-five patients in whom early excisions were made, thirty-eight had bone complications, six suffered amputations and two died.

Tracing them further from the standpoint of secondary surgery, we find that forty-seven wounds healed cleanly, demanding no surgical interference; four demanded secondary aspiration, all of them giving good results, and thirteen demanded secondary operation, six of them being the amputations mentioned in the foregoing.

The general results of the series of eighty-five were excellent in twenty-five instances; good in thirty-six, fair in thirteen; loss of limb in nine, and death in two.

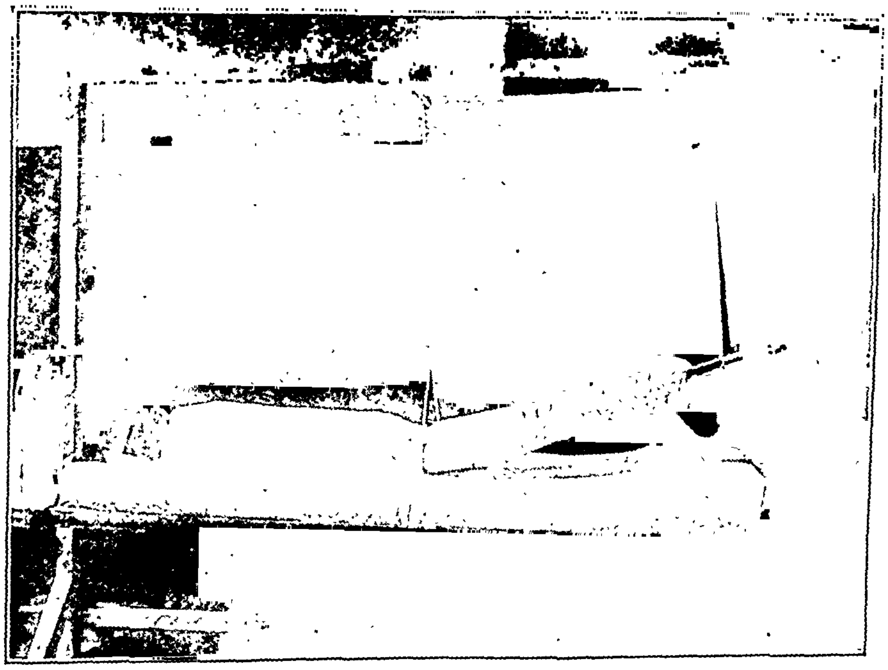

Fig. 2.—Prone position with subcrural drainage. When turned, the Thomas splint is easily supported by the same ropes.

GENERAL DIRECTIONS

In the light of results of recent experience, after a knee joint injury, the soldier should be splinted at the first dressing post and not be allowed to walk on the leg. All operations should be done at the casualty clearing stations, within twenty-four hours after the wound is received, when possible, or better yet, within eight hours. During pushes, this arrangement is not possible, as a selection of patients for the base hospital must be made. Under such severe battle circumstances, the following types of knee injury may be evacuated at once.

1. Wounds which show no inflammation, are quiescent, and lack pain.
2. Small clean wounds of entrance and exit, or entrance alone, probably caused by rifle bullet.
3. Wounds with no serious bone or blood vessel complications.
4. Wounds in which foreign bodies are not evident and the joint is not painfully distended.

Wounds of the posterior aspect of the knee are more favorable for transportation, since they drain out by gravity. On the anterior aspect, they may drain into the joint during the journey. The Thomas splint, with extension and flannel bandages from toe to thigh, should be used.

Types of knee injury to be retained at the casualty clearing station are:

1. Those complicated by serious bone or blood vessel injury.
2. Distended painful joint, or early signs of septic inflammation.
3. Foreign body visible or palpable after it has opened joint.
4. Large superficial wound generally caused by shell fire, opening into the joint. Sepsis is certain to spread into the joint and immediate operation is wanted.

Early operative treatment is either radical or conservative. Radical treatment calls for either amputation or resection.

Amputation is advised if severe blood vessel injury exists, or even a large hematoma with probable infection in the popliteal space; if severely comminuted fractures into the joint exist; if gas infections of the periarticular tissues are present, or if sepsis has already set in, and the patient is in a poor general condition. Resection is advised if a comminuted fracture leaves little normal joint surface. Most of these fractures result later in amputations. Only those that are resected very early do well.

Conservative treatment is reserved for the penetrating and through and through wounds, even in the presence of fractures not sufficiently extensive to indicate resection or amputation. If the patella is shattered, it is removed, its periosteum is spared, and the synovial membrane is closed, if possible. If the presence of a foreign body is even suspected, the patient should not be operated on until there are roentgenograms in both lateral and anteroposterior planes.

OPERATIVE TECHNIC

Every knee joint gunshot wound should be operated on if time and circumstances permit. The most innocent appearing may lead to serious trouble. The successive steps are as follows:

1. First come careful skin shaving and disinfection. The leg should be held up off the table by an overhead swing.
2. The track of the missile is completely, carefully and slowly excised with a sharp scalpel, but no scissors. The sliding of the tissues over each other is avoided and the contused edges are removed in one piece. Sufficient skin opening is made to permit access to the foreign body or the joint surface. Fresh towels and instruments are then displayed. No fingers or instruments are inserted through the solid wound into the joint, since not only may infection be carried in, but the foreign body may be pushed into an inaccessible area. The comminuted bone and foreign bodies are removed. The synovial surface should not be sponged, or irritated or exposed for any longer time than necessary. It matters little about the length of the skin incision, but the amount of skin removed should be sparing to avoid undue tension in the

closure. Skin plastics may be performed. If the foreign body is buried in bone, it is removed, and with it the surrounding damaged bone.

3. The joint may be irrigated with physiologic sodium chlorid solution. Various operators use ether, flavine, proflavine or eusol. As far as I can tell, the solution used makes little difference. Mechanical cleansing without joint trauma is desired.

4. The wound is closed in layers. The synovia is closed by stitching, to bring only smooth surfaces in contact, and the skin and superficial tissues are closed snugly unless there is great edema and contusion. In that case, a small drain may be put down to the closed synovial surface, not into the joint. If the synovia cannot be closed, a gauze pack is placed down to its surface. Injection of formaldehyd solution, glycerin, ether or other irritants into the closed joint is of doubtful value.

5. A Buck's extension is attached to a Thomas splint on the leg, and flannel bandages cover all. For comfort and steadiness, the application of the splint should be exact, requiring skilled attention. Most patients should be retained from twenty-four to forty-eight hours before transportation. Dressings and splints are not disturbed unless there is pain, fever or looseness.

Each operation takes from forty minutes to two hours. When aseptic healing is in progress and the joint is not painful, slight passive motions may be started, the second week. Should the joint become distended, should temperature rise and sepsis seem to be starting, an aspiration may be performed to decide the character of the intra-articular fluid and to obtain a culture. Staphylococcus infection is less to be feared than streptococcus. With rest, it may even subside after aspiration. Objections to aspiration are found in the wounding of the synovial surface and leakage of the infected joint contents through the puncture hole into poorly resisting periarticular tissues, resulting in a rapidly spreading sepsis. The joint surface has as much resistance as, if not more than, the periarticular tissues.

Why should these wounds be excised, the synovial edge trimmed and the joint irrigated, after the foreign bone fragments are removed? Because, without a doubt, the synovial surface is almost as able to take care of itself as the peritoneum, if given a chance, and the resistance of the joint surface is greater than we have been led to believe. After trimming and irrigating, the operator closes the joint snugly, and its own resistance will often do the rest. If the joint is not so treated, and if it opens into the unexcised tract of a missile which becomes septic, it is ultimately contaminated by the extension of the infection. This fact can be proved by many clinical observations, the joint infection coming on late after the wound infection has developed and seeped into the articular surface. This is what happened to most of the septic joints in the early part of the war. If infection arises extra-articularly from the closing of the joint after wound excision, it is recognized and the joint is drained, and thereby saved. We employ this principle constantly in operations in fractures of the patella. Splinting prevents motion, and hence favors an early healing of the sutured synovia. It also saves the patient from pain and loss of sleep — two important factors, if sepsis supervenes.

One has only to follow these patients from clearing station to base hospital to be convinced of the value of this treatment, even if gross statistics did not confirm it fully.

TREATMENT OF SEPTIC JOINT

When septic joint threatens to follow conservative treatment, or no operative treatment at all, what shall be done? Gray,[2] and Rankin[3] advise early radical incision and drainage. I am inclined to side with Page,[4] who says that no classical drainage of the knee joint is satisfactory and that joint excision after infection is valueless. Early amputation is advisable. Amputation must be looked on as a means of saving life. Long courses of joint sepsis, despite radical drainage, give too high a mortality. Early amputation gives a lower mortality and a satisfied living patient. Not that every septic knee should be amputated, but it is probably true that more should be so treated. The joints are drained repeatedly until the patient's resistance and vitality are so low that late amputation results in death or generalized sepsis. A drained joint may result in a useless leg which must be removed within a year.

In July and August, 1917, I began to drain these septic knees very early through the upper part of the subcrural pouch. A small rubber tube was introduced into the joint just after aspiration and the making of a confirmatory culture. Remarkable relief followed the small incision and drainage. Some patients went on to recovery, but others had to endure more extensive drainage or amputation. It was finally decided to drain them thus very soon after cultural proof of intra-articular infection has been obtained, and then, with the leg firmly held in a Thomas splint, to turn the patient over on his face in order to let the joint exudate run out of the small opening, which in this way has become the most dependent point of the joint. The entire joint surface, even down between the bones and the crucial ligaments, was thus drained. When the patient is in dorsal decubitus, it is difficult to drain the knee joint completely, on account of its topography. Lateral incisions must be made very low down and must be sufficiently extensive to drain both the subcrural area and the real joint surface. No knee joint that I have dissected has failed to show full and open connection between the articular surface and the subcrural pouch. Localized infections of the knee joint are almost impossible. Many times in necropsies on these amputated legs, fresh fibrinous or even fibrous adhesions walling off pockets have been found, but the whole joint was also infected. Lateral plus transverse incisions, through the lateral ligaments at the joint level as far down as is safe in order to avoid important structures, will still leave a pocket for the accumulation of pus, but may save a joint. Some joints among this series of patients were saved by this precaution. The crucial ligament should be cut across at the same time, if a stiff knee is anticipated.

For the first stage of knee joint infections, however, even for those that threaten to become severe, subcrural drainage and inversion treatment are suggested. I was ordered to a casualty clearing station in August, and a serious trial of this treatment was interrupted until my return to the base hospital in October. In that month, Mayo-Robson[5] also advised the use of this method, but did not state whether he had attempted it. At that time, there were three patients under treatment for knee joint infection in one of my wards.

SUBCRURAL POUCH DRAINAGE AND INVERSION TREATMENT

The joint is proved septic, and should be taken at the earliest stage. Under anesthesia, an opening 1 inch long is made in the midline of the thigh at the upper margin of the pouch. The quadriceps extensor muscle fibers are separated longitudinally by a pair of Mayo scissors, and the joint synovial surface is carefully opened through its upper reflection only. The lower synovial wall should not be damaged. A medium-sized rubber tube extending just into the joint is sewed into place (Fig. 1). The incision around the tube is left wide open to permit the secretion to run out, instead of backing into the thigh tissues. A Thomas splint and extension are applied, the leg being supported by cross pieces of perforated metal both anteriorly and posteriorly, and being thoroughly padded and so bandaged that the portion over the wound can be removed for dressing without loosening the splint. The patient is then put to bed, a Balkan frame is rigged over him, and for a couple of hours night and morning, he is turned over on his face (Fig. 2). Later these periods are extended until he can lie thus for hours at a time.

If the tube clogs with pus and débris, it can be mechanically washed out with physiologic sodium chlorid solution or eusol until it is freely open. The joint may thus be partly irrigated, if desired. When the discharge becomes serous, pus ceases and temperature falls, the tube is removed and the small wound is allowed to heal, the joint being safely started on its own resistance looking toward recovery. The splint is, of course, retained until the joint is quiet and painless.

Six patients have been treated by this method of drainage and inversion and observed for a long period. In four cases the results were very good, one patient recovering from a gas infection of the joint. One had a doubtful outcome and one required amputation. There seems to be a distinct field for this type of treatment, which necessitates comparatively few operations on patients who would otherwise be subjected to extensive drainage, incisions and prolonged suppuration.

Patients so treated should be in the early stage of joint infection, before erosion of the cartilage has taken place and before the infected contents of the joint have mechanically burst or pathologically necrosed through the synovial surface to set up a suppurative periarthritis. This early attention is all-important. If the infection is retained within the joint surface, the synovia, with the help of sensible gravity drainage for its exudate, will rise nobly to do battle. If the periarticular surfaces are also seriously invaded by the pyogenic infection, we cannot expect joint drainage alone to produce a subsidence. It is important, therefore, to follow a technic as described. The operative opening into the joint must not open an avenue for infection into the thigh. In one instance, a secondary and, fortunately, a superficial thigh abscess had to be evacuated after the joint had quieted down. Drainage tubes must be given careful attention, the character of the discharge must be noted, and the tube removed as early as consistent. A bacteriologic control of the joint discharge might aid. A snug splint will not allow knee motion. The patients need encouragement and even anodynes when they are first turned over, but they are soon willing to help turn themselves, understanding that a special effort is being made to save them from more serious operation or amputation.

A vertical position of the limb at right angles to the body in the Thomas splint also places the subcrural pouch in a dependent position, but the drainage is not absolute as in the prone position, and there is more tendency for progressive infection of the thigh tissues.

RULES FOR TREATMENT OF WAR WOUNDS

The following principles governing treatment of war wounds of the joints were adopted at the Inter-allied Surgical Conference, in March and May, 1917. They corroborate some of the facts set forth in this article.

1. At the dressing station, wounds of the joints should be immobilized with great care, in an appropriate apparatus.
2. At the clearing station, all injured joints in which the wound is extensive, the joint tissues are lacerated, or the missile is retained, and especially when a fracture is present, should be operated on, if possible, during the first six or eight hours after the patient's arrival. The French surgeons extend this rule to all cases, except certain bullet wounds with a punctiform orifice and without fracture.
3. Roentgenoscopy is indispensable in every case.
4. The operation should include a wide aseptic arthrotomy with excision of the tract, a complete exploration of the joint, a systematic removal of foreign bodies and splinters, and a cleaning and curetting of the lesion in the bone. This should be followed either by complete closure, or by closure of the capsule with superficial drainage. A compressing dressing should be applied.
5. Resection, typical or atypical, should be practiced only when there is considerable damage to the bone. In the knee, the operation should be primary, whereas in the elbow and shoulder a secondary operation is preferable.
6. In severe suppurative arthritis, the first measure should be a wide arthrotomy with complete immobilization and progressive disinfection of the wound. If this treatment fails, then resection should be practiced, with separation of the articular surfaces by extension. In very grave cases immediate resection is required.

REPORT OF A PATIENT ON INVERSION TREATMENT

Patient 56 in series, a driver R. J. O., 1722, A. F. A., Forty-Third Battery, sustained a shell wound of the left knee. The usual excision treatment was performed at the casualty clearing station, and two days later he was admitted to General Hospital No. 18. The following day his temperature rose to 102.2 F. The knee was painful, and aspiration of the joint revealed a cloudy sanguineous fluid which on culture showed the staphylococcus. The next day's notes said: "The knee joint area as a whole is slightly swollen, edematous and distended. Subcrural pouch not tender to pressure. On the inner side of the joint over the head of the tibia is a slightly ragged wound (stitches removed) discharging pus. This does not seem deep, and the puffiness around the anterior knee tissues extends to the tibial tubercle. The joint was closed off by the primary operation, but while undoubtedly involved (the culture showed organisms) the ultra-articular infection does not appear virulent. Temperature, 100.4. It is possible that the condition is an osteomyelitis of the tibial head as the roentgen ray shows a grazing damage of the bone. A natural reaction within the knee may save it. Skin wound opened widely and hot dressings applied."

Two days later it was necessary to drain the joint, the subcrural pouch was opened, and the patient was put on inversion treatment. After six weeks, the notes said: "Temperature about normal for past thirty days. Slight swelling about the knee, and the wound is practically closed. The patient's general condition is very good, the joint is quiescent and will probably be stiff.[6] Evacuated to England."

Special Article

SYNTHETIC DRUGS III[*]

JULIUS STIEGLITZ, Ph.D., Sc.D., Chem.D.
CHICAGO

Since the publication of the last article in this series, information supplementary to that given previously has been received as follows:

Neo-Arsphenamin.—An importing license has been granted by the Federal Trade Commission to the Diarsenol Company, Inc., 475 Elicott Square, Buffalo, for the Canadian brand of neo-arsphenamin, Neodiarsenol. Licenses for neo-arsphenamin have also been issued to the Takamine Laboratories, New York; Farbwerke-Hoechst Company, New York, and Dermatological Research Laboratories, Philadelphia. The price has not been fixed as yet, but the understanding is that the market price will be about $2.25 per 0.6 gm. ampule.

Holocaine Hydrochloride (see Article II, p. 689).—This may be obtained from the Farbwerke-Hoechst Company, 111 Hudson Street, New York, which still has supplies of the German-made article at the price of 50 cents and 45 cents per gram in containers of 1 and 5 gm., respectively. As the drug may be easily prepared from acetphenetidin, the manufacture of the product in this country with a view to its sale at a lower price is being encouraged.

Barbital-sodium, introduced as veronal-sodium (see Article I, p. 537), has been submitted by the Abbott Laboratories, Ravenswood, Chicago, under their license to manufacture barbital, and is being examined by the chemical laboratory of the American Medical Association.

THE STATUS OF SYNTHETIC AND RELATED DRUGS CONSIDERED ESSENTIAL (CONCLUDED)

6. *Cardiac Stimulants.*—Caffein and its combinations with sodium benzoate, citric acid, etc., is available from a number of American firms. No shortage has been reported.

Ouabain (G-Strophanthin-Thoms; crystallized strophanthin) is being supplied in ampules by Hynson, Westcott and Dunning, Baltimore, who are enjoying the counsel of Prof. R. A. Hatcher of the Cornell University Medical School in controlling the purity and the keeping quality of their preparation. Merck & Company report their stock as exhausted and not likely to be replenished in the immediate future. The committee has been endeavoring to interest another large manufacturing house in this drug because it is not considered in the interest of the public welfare that the country should be dependent on any single source of supply in the case of any essential drug, any source of supply being exposed to destruction by fire or other calamity.

In those few cases in which the drug digitalis or its galenic preparations cannot be used, digipuratum and digitoxin are available in good quantities from Merck & Company, 45 Park Place, New York, and digipoten from the Abbott Laboratories.

Attention is called here to the report on the therapeutic use of digitalis preparations by Dr. R. A. Hatcher,[1] which was written at the request of this committee to help meet the present emergency situation.

7. *Local Antiseptics.*—Of the various preparations containing colloidal silver or silver in combination with a protein, quite a number are normally manufactured in this country, and physicians should have no difficulty in securing supplies. Thus silver protein, Squibb (E. R. Squibb & Son, New York), Argyrol, a silver vitellin (manufactured by the A. C. Barnes Company, Philadelphia), Novargan, a silver proteinate, and Collargol, a colloidal silver preparation (both manufactured by the Heyden Chemical Works, Garfield, N. J.), Protargol, a silver proteinate (manufactured by the Bayer Company, Inc., New York,), and Cargentos, a colloidal silver oxid (prepared by the H. K. Mulford Company, Philadelphia) may be mentioned in this class.

The various antiseptics based on the work of Dr. Dakin and Dr. Carrel are now manufactured in this country. The preparations of the Calco Chemical Company, Bound Brook, N. J., the Monsanto Chemical Company, St. Louis, and of the Abbott Laboratories, Ravenswood, Chicago, have been accepted as of standard strength by the Council on Pharmacy and Chemistry. New and Nonofficial Remedies, 1918, contains standards for these products.

8. *Varied.*—There has been considerable inquiry for guaiacol preparations. The Lyster Chemical Company, 61 Broadway, New York, is said to be making a specialty of these preparations. The manufacture of these products as well as of the derivatives of creosote has been recommended to a number of firms.

The supplies of the important *mydriatic* euphthalmine (see New and Nonofficial Remedies, 1918, p. 55) are reported as exhausted, and the former agents of the German preparation, Schering and Glatz, have stated that they do not contemplate manufacturing the product. As this drug is used only in small quantities, too small apparently to interest commercial houses, arrangements are being made to have it manufactured in a university laboratory under license of the Federal Trade Commission.

The manufacture of salophen is being studied by the Antoine Chiris Company, New York, and in the chemical laboratory of the University of Chicago work on the process is being carried out with the view of insuring better yields in its manufacture.

Physicians interested in products which they may consider essential and which have not been referred to in this series of articles, and physicians who have reason to believe that extortion is being practiced in the charges for any synthetic drug, are urged to communicate with the author, whose committee will be glad to give the reports careful consideration.

---

[6] A letter from the patient states that he is gradually acquiring the use of the joint.

[*] The information conveyed in these articles is based on the latest reports to the writer; it is probably not complete as to all details, but is published now to avoid further delay in bringing the main facts before the medical profession. The writer will be glad to receive information to be used later according to his best judgment.

RESPIRATION AND THE CARBON DIOXID CAPACITY OF THE BLOOD

The more recent study of what is commonly termed acidosis has shown that the underlying phenomena that may be postulated to explain it are far more diverse and complex than was formerly assumed. The original conception was primarily concerned with the excessive production of acid in some form or other in the body. Subsequent investigations have made it clear that the organism has an unexpectedly large capacity for maintaining its neutrality, despite the appearance of unusual quantities of acid. This forms one of the conspicuous factors of safety. One acid factor is constantly present in the form of the continually produced carbon dioxid. It is carried away from the cells in the tissue fluids and blood in solution as sodium bicarbonate, and the excess can be promptly eliminated through the process of breathing, thanks to the usual responsiveness of the respiratory center to even the slightest increment in acidity in the circulation. Acids other than carbonic displace the carbon dioxid from the blood, so that the total acid factor present is scarcely altered from the standpoint of hydrogen ion concentration. Owing to this regulatory mechanism, it is practically impossible to detect any undue production or accumulation of acids in the blood by estimating its reaction; for the balance of acids and alkalis is kept essentially unaltered until very extreme conditions arise. These facts have often been emphasized in The Journal.

When other acids displace part of the carbonic acid of the blood, the carbon dioxid tension of the blood decreases; and since the carbon dioxid tension of the alveolar air varies directly with that of the arterial blood, it has been customary to estimate this respiratory factor as a measure of acidosis. Lately, however, attention has been centered even more on the altered capacity of the blood plasma to bind carbon dioxid when acid production is increased in the body. If the available bases neutralize other acids, they cannot combine with their usual quota of carbonic acid. D. D. Van Slyke, in particular, has emphasized the importance of measuring the carbon dioxid combining capacity or the "alkali reserve" of the blood as an index of acidosis more reliable than the estimation of the content of carbon dioxid in the alveolar air.

Yandell Henderson[1] and his collaborators have pointed out that alterations in respiration introduce still further complicating factors into the problem of estimating the existence of acidosis. It is shown by them that when in an otherwise normal organism respiration is stimulated to excessive vigor by pain, or by a drug like ether (or probably by any condition that lowers the threshold and increases the sensitivity of the respiratory center), the blowing off of carbon dioxid produces a reduction in the carbon dioxid content of the blood. This condition very soon leads to (and in respect to p_H is probably in part compensated by) a reduction also in the carbon dioxid capacity (alkali reserve) of the blood. Apparently alkali passes out of the blood into the tissues. Thus the acid-base equilibrium, or carbon dioxid alkali balance, of the blood is restored at a level much below *normal, and* a condition simulating true acidosis, but *in certain* respects markedly distinct from it, results. The feature to be emphasized is that the content of *not only* the carbonic acid but also the sodium carbonate remains low. Henderson believes that, unlike a true acidosis, the total alkali in the body remains, so far as we can judge, unaltered; it is merely abnormally distributed. A reversed condition is brought about by diminished breathing. When the respiratory center is depressed, as by morphin, says Henderson, or when, by the administration of high concentrations of carbon dioxid in the air breathed, the alveolar carbon dioxid is raised, the carbon dioxid content of the blood is also raised. This causes (and in respect to the p_H of the blood is probably compensated by) an increase in the carbon dioxid capacity or "alkali reserve" of the blood, due apparently to the passage of alkali from the tissues into the blood. Thus a pseudo-alkalosis or, if one thinks only in terms of p_H, a carbon dioxid acidosis, is produced. Here both the carbon dioxid and the sodium carbonate in the blood are above normal. Probably, we are further told, the total alkali in the body is unaltered and is merely redistributed.

The views just outlined place primary emphasis on alterations in breathing rather than on metabolic changes as the starting point of alterations in the carbon dioxid carrying capacity of the blood. Henderson and Haggard,[1] working at the Yale Medical School, have tested their hypotheses in relation to the known phenomena of ether anesthesia. According to them the disturbance of the carbon dioxid capacity of the blood by ether appears from these experiments to be wholly dependent on disturbance of respiration. If the anesthesia is managed so that respiration is but little increased, the lowering of the carbon dioxid capacity of the blood is slight. Ether hyperpnea, however, causes a very great reduction. Down to the critical level between 33 and 36 per cent. by volume, the process is spontaneously reversible and the animal recovers. Below this level it appears to be irreversible, and death ensues. According to the Yale physiologists, light etherization, such as is otherwise most effective in lowering the carbon dioxid capacity, and most harmful to the subject, loses this influence when administered with sufficient carbon dioxid to maintain the alveolar carbon dioxid at a normal level.

---

[1] Henderson, Yandell, and Haggard, H. W.: Respiratory Regulation of the Carbon Dioxid Capacity of the Blood, I, High Levels of Carbon Dioxid and Alkali, Jour. Biol. Chem., 1918, **33**, 333; II, Low Levels of Carbon Dioxid and Alkali Induced by Ether: Their Prevention and Reversal, ibid., p. 345; III, The Effects of Excessive Pulmonary Ventilation, ibid., p. 355; IV, The Sequence of Trauma, Excessive Breathing, Reduced Carbon Dioxid Capacity, and Shock, ibid., p. 365.

Henderson has long insisted on the dangers underlying overventilation in anesthesia, owing to the acapnia that results.[2] The sequence of events to be taken into account are thus summarized by him: Under ether the alkali reserve of the blood follows and is controlled by the carbon dioxid content, and the carbon dioxid content is in turn dependent on the alveolar carbon dioxid, which is determined by the breathing.

INTRAGASTRIC CONDUCTANCE

The introduction of the stomach tube as an instrument for use in clinical diagnosis is sufficiently recent to enable many of us to recall and survey from personal recollection the helpful contributions which this aid in technic has afforded. It is one of many devices and procedures that have tended to make possible more accurate measurements in a field in which guesswork and assumption previously prevailed. History shows that every instrument of precision applicable in medicine has tended to advance our science and practice to a decidedly higher plane; this is true likewise of devices that permit the application of more exact methods of analysis. It is worth while, perhaps, to emphasize this fact; for one might hastily conclude that progress in the development of instruments and instrumentation has been applicable solely to surgery or mechanotherapy. As a matter of fact, the catheter, the trocar and the gastric sound are useful alike for diagnostic and for therapeutic ends.

The employment of newer forms of instruments, like the duodenal catheter and the modified gastric tube of Rehfuss, have facilitated chemical exploration of more remote portions of the alimentary tract, in the one case, and the removal of contents at frequent intervals, in the other instance. Here, evidently, greater accuracy in analysis of samples of contents, and consequently a clearer insight into the sequence of secretory and digestive phases, have been made possible. The device for the determination of intragastric conductance newly described by Bergeim[3] of the laboratory of physiologic chemistry at the Jefferson Medical College, Philadelphia, gives promise of additional helpfulness in the same field of clinical investigation. It consists of a retention stomach tube in the form of an electrolytic cell which permits the determination of intragastric conductances at any desired interval of time without disturbance or removal of gastric contents. The tip of the device contains a thermocouple which makes possible intragastric temperature determinations and corrections, and an aspiration tube by means of which samples of gastric contents may, if desired, be collected for analysis.

The usefulness of the intragastric conductance apparatus as an aid in diagnostic gastric measurements depends on the fact that the conductance of most biologic fluids is dependent on their content of salts of strong acids and bases. The specific conductance of any solution depends only on the number of ions present and the mobility of those ions, being thus more specific than the cryoscopic index, which is influenced also by the molecules of undissociated substances. Strong acids and bases or the salts of strong acids and bases are very completely dissociated in solution in the concentrations commonly encountered in physiologic fluids. Weak acids and bases and their salts are but slightly dissociated, and neutral organic substances, not salts, do not ionize. These facts led to the hope that estimations of conductance might in many cases at least furnish an index to the concentration of hydrochloric acid in the stomach. Bergeim pointed out that a determination of this character would possess the advantage over titration methods of obtaining the desired data at as frequent intervals as required without any disturbance or removal of gastric contents.

Test experiments have apparently demonstrated the value of the new procedure. Bergeim has already noted that aside from the swallowing of saliva, the conductance of which is low, intragastric conductance, after the first hour or so of digestion, is almost always considerably modified by the regurgitation of pancreatic juice or bile or both, and possibly to a lesser extent by pyloric and duodenal secretions. The conductance of pancreatic juice and bile being usually very low as compared with that of the gastric contents at maximum acidity, regurgitation tends markedly to lower intragastric conductance as well as activity. Conductance, however, rises relative to free hydrochloric acid, on account of the higher salt content of these regurgitated secretions. After the ingestion of mineral acid, neutralization is brought about in the same manner as during digestion. The progress of these studies of the gastric response to food and intragastric digestion, examined in new ways, will be watched with interest.

LEGISLATION FOR INCREASED RANK FOR MEDICAL OFFICERS

On several occasions The Journal has emphasized the importance of legislation for increased rank and authority for officers of the Medical Reserve Corps. Specifically it has urged enactment of the recently introduced Owen-Dyer Bill. It has been suggested that modification of this bill would be necessary to secure its passage, but that such modification need not be serious. In any event, some such legislation is not only desirable, but also vitally necessary if common justice is to be rendered to the Medical Reserve Corps, and if the best results are to be achieved by the Medical Department. Apparently the only active opposition thus far has come from the general staff and the Secretary of War. If the newspapers of the country mirror public opinion, certainly the public is in favor of this legislation.

As the Brooklyn *Eagle* says, "The logic of this proposition appeals to every mother whose son is in a home camp or in the country's service abroad. It is inexorable logic. All that the Owen Bill, now pending, does is to give Army surgeons the ranks corresponding to those the Navy grants. It is not a radical, not a revolutionary measure, but it will put an end to conditions greatly injurious to the health protection of American soldiers." The Buffalo *News* thinks that "inasmuch as the measure is calculated to facilitate the work of the Army Medical Corps and benefit the troops by precluding dangerous delays in medical relief, etc., its passage will be welcomed and approved of by every one," and the New York *Globe* states that "the request of the officers of the Medical Reserve Corps to be placed on the same footing as the regular Army medical officers seems to be a perfectly reasonable one. . . . The call of the Army to the medical profession has been enthusiastically responded to. . . . Remediable legislation ought to be enacted without delay and the doctors of the country should help the volunteering members of their profession to win the recognition to which they are entitled by urging their representatives and senators to support the Owen-Dyer Bill." The Chicago *Herald* presents the case for both sides, and states that "lives can be saved and the strength of the Army kept up, medical men think, more easily if greater power commensurate with responsibility were in the hands of the doctors and sanitarians. A decision should be reached without prejudice, and unless it can be lucidly shown that higher ranks for medical officers can have definite disadvantages, General Gorgas' bills should be enacted." The Boston *Herald* notes that the cream of the medical profession of the United States is now included in the Medical Reserve Corps. "They labor under a serious handicap by reason of their inferior rank. . . . Titles ought to correspond to responsibilities. . . . When we realize that in all our wars disease has been responsible for more than 70 per cent. of the mortality, we can get some realization of the importance of the service which we call on the Medical Reserve Corps of the Army to render." The Philadelphia *Record* doubts whether Secretary of War Baker is "seriously against" the legislation. "From an unprejudiced point of view," it says "there would seem to be no good reason why physicians and surgeons who are rendering invaluable service in saving lives and protecting the health of the soldiers should not be raised to a rank commensurate with the importance of their work, especially if that is the case in other armies than our own. The opposition to this apparently simple act of justice betrays the same spirit which fought against the idea that enlisted men in the Army and Navy should be given every opportunity to rise to the highest honors."

In fact, the press is practically unanimous in favoring this legislation. With this encouragement, the physicians of the country should redouble their efforts to let Congress know that the medical profession wishes an early and favorable consideration of legislation for fair treatment of their confrères in military service.

Current Comment

WARTIME ATTITUDES TOWARD DIETARY REFORMS

Any careful observer of the effects of the conditions that the war has brought about in relation to food and diet may observe at work two somewhat contrary tendencies. For one group of our population, representing the most conscientious endeavor to "do one's duty" in the face of the admonition that food will win the war, there is actually a danger of self-imposed denials that may be detrimental to the best welfare of its members; whereas another group, enjoying perhaps for the first time the advantages of high wages and larger incomes, feels the temptation to indulge in unwonted dietary extravagances. The time has come when the indifferent representatives of the latter group must be brought to a realization of their full duty. On the other hand, it may well be asked whether the earnest conservationists are not in danger of impairing their health and vigor by undue dietary restrictions and unwonted substitutions that may lead to lack of appetite and insufficient food intake. Dr. Percy G. Stiles[1] of the Harvard Medical School has given some timely advice to the zealous lest they impose on themselves extreme and ill advised denials. Since a considerable part of our food intake is utilized as fuel to support muscular activity, the added needs of all persons who are engaged in strenuous work must never be forgotten. Sugar furnishes nearly one seventh of the total energy of the American people. As Stiles puts it, the replacement of this is an operation of vast magnitude. We must also bear in mind, what has repeatedly been emphasized by The Journal, that the food needs of growing children are proportionately large, so that they must not be restricted in proportion to their size. An adolescent boy may require more food than a hard working man. Even in war time health and vigor must be conserved in fullest measure, for only thus can the best service be rendered. In making the new adjustments of these days, it is above all essential to preserve a proper mental balance. Hence we commend this salutary advice by Stiles:

---

[1] Stiles, P. G.: War Time Diet and Health, Health News, 1918, **13**, 28.

> It is within our power to determine whether we will magnify our privations or find an intellectual pleasure in grasping the problem and watching the process of its solution. We may dwell on the unwelcome restrictions or we may with greater advantage rejoice in the new spirit of cooperation. It is likely enough that the dissatisfaction we are tempted to feel with our daily food arises chiefly from the unhappy undercurrent that is in every mind. The terrible facts of the war are to be resolutely faced, but we shall do well to preserve our mental balance by sane recreation, good reading, and other interests detached from this colossal horror. If we can keep a philosophic temper we can make light of dietetic trammels.

WATER WASTE IN CHICAGO

Chicago pumps from Lake Michigan a daily average of 259 gallons per capita. This is the largest amount of water furnished by any waterworks system in the world. The original character of Lake Michigan water is exceptionally satisfactory, but at times the water near the shore becomes more or less contaminated by neighboring towns and to some extent by the city itself. The water supply is not contaminated uniformly and continuously, but its pollution depends largely on weather conditions and the presence of passing vessels. At times also the water becomes highly turbid, owing to the stirring up of the lake by storms and by temperature changes. It is believed by many authorities that eventually Chicago will demand filtration of the supply in order to eliminate impurities and excessive turbidity. The expense of filtering the enormous volume of water now pumped is practically prohibitive, and it would seem as if the volume should be materially reduced if filtration is ever to be carried out. There is no question that a large part of the water pumped through the mains of Chicago is wasted — not used. If the pumpage could be reduced to 125 gallons per capita, a substantial saving would be effected. Cleveland and Milwaukee, also large industrial cities on the Great Lakes, report a daily pumpage per person of 113 and 118 gallons, respectively. It is estimated that nearly 100,000 tons of coal annually are wasted at the Chicago pumping stations in pumping the unnecessary quantity of water that now passes through the mains. All responsible waterworks superintendents and engineers are agreed that the only remedy for this situation is the establishing of universal metering as a policy. It is hardly necessary to point out that metering does not restrict the proper use of water, but merely diminishes the waste. Universal metering in Chicago would also insure an abundant supply at sufficient pressure for all consumers in all parts of the city. It is estimated that in thirty-three years universal metering will save the city $135,000,000. Additional tunnels, cribs and pumping stations will not be needed throughout this period. The prejudice that exists against metering in some quarters is unreasonable and not based on facts. Here is an important measure of conservation which in the long run will be of advantage to the health as well as to the finances of the whole community. The movement to meter the water supply of Chicago should have the active support of every physician.

BONITA, THE BEAUTIFUL

Last week the Propaganda department had a brief history of the Braun family, "Professor John F., Himself," and "Professor Kate A., Herself," now of Peru, Ind. The number of aliases assumed by this family of quacks was mentioned and some of the names were given. Braun for a while called himself "Rev. D. R. Schiller"; Mrs. Braun has appeared under many names, some of them being "Delia Deimling," "Hulda De Muth" and "Mary A. Rose." The latest name with which the Brauns juggle seems to be "Bonita." Now come some Indiana newspapers recording the arrest at Rochester, Ind., of "Miss Bonita Rose of Peru and her brother Oliver Rose." According to the papers, "Bonita . . . enjoyed a few days of fine business" and "it is thought the couple extracted about $500 for their few days service in Rochester." The advertising matter announcing Bonita's coming indicate that "Professor Braun, Himself," had not lost his old skill as a press agent. Here is a sample:

> "Bonita, a noble, beautiful character, was born of poor parents in an obscure American village. This sweet and unpolluted flower of love and kindness has sympathies as wide as the world. She is a perpetual surprise, even to those who know her best. And there is something about her no one has ever been able to explain, not even herself."

This beautiful "unpolluted flower"—whose "mother, Mrs. Mary Rose . . . is also a 'healer' "—is out under bond. The case was set for a hearing March 27.

LITERATURE ON RECONSTRUCTION AND REEDUCATION

Among the recent bulletins on reconstruction and reeducation of the disabled soldier to reach The Journal is the March, 1918, number of "Reconstruction," a bulletin issued by the Invalided Soldiers Commission, 22 Victoria Street, Ottawa, Canada. It is well illustrated and in addition to special articles on various phases of the work, contains news items, question and answers, and contributions from disabled soldiers presenting their points of view. Another series includes Nos. 4 and 5 of the bulletins issued by the Red Cross Institute for Crippled and Disabled Men, New York City. No. 4 is entitled "A Statistical Consideration of the Number of Men Crippled in War and Disabled in Industry," by I. M. Rubinow. The contents are well described by the title. No. 5, a pamphlet of seventy-five pages, is written by Major R. L. Todd of the Canadian Army Medical Corps, and is entitled "The French System of Return to Civilian Life of Crippled and Discharged Soldiers." It is a complete study of French methods and experience in this work. Bulletins 5 and 6, issued by the Federal Board for Vocational Education, have also just come to hand, the former entitled "Vocational Rehabilitation of Disabled Soldiers and Sailors" based on a study made by Dr. John Cummings, and No. 6, "The Training of Teachers for Occupational Therapy for the Rehabilitation of Disabled Soldiers and Sailors," by Elizabeth G. Upham. Bulletin No. 5 is divided into five parts, the first concerning general principles and policies; the second a complete review of foreign legislation and experience; the third, the size of the problem; the fourth, an outline for an exhaustive study and report, and the fifth, a reprint of the bibliography of the war cripple compiled by Douglas C. MacMurtrie of the Red Cross Institute for Crippled and Disabled Men. The contents of Bulletin 6 are indicated by the title. These pamphlets may be secured by writing to the Federal Board for Vocational Education at Washington. The division for reconstruction and reeducation of disabled soldiers of the Surgeon-General's Office of Washington has issued two bulletins, in mimeograph for Army use only, consisting of abstracts, translations and reviews of the recent literature on this subject. The first bulletin was issued in January and the second is just received. Together they bring the subject up to date. The recent publications here mentioned are only a few of the many that have been issued since the beginning of the war. Even a cursory reading emphasizes the much to be regretted fact that the great bulk of this material is reduplication. What is needed today, particularly in this field, is coordination and cooperation. Let us emphasize: coordination is especially needed in the literary field. Such reduplication means not only waste of work and expense, but also discouragement for those who are interested in this tremendously important subject.

Acetic Acid and Acetone from Beets.—G. Mezzadroli, an Italian scientist, conceived the idea of utilizing the bacilli contained in both sour milk and beet juice in directly transforming the saccharose in beet juice into lactic and acetic acids as by-products in the manufacture of alcohol and sugar. The bacilli concerned as he designates them are lactic acid invertors and acetic acid invertors. The details of the conversion are given in the *Scientific American*, March 9. Beet juice containing about 10 per cent. of sugar is sterilized for half an hour at 120 C. and then planted with a pure culture of the lactic acid convertor which in a few hours causes it to become highly acid. After several neutralizations with sterile sodium carbonate the acid formation ceases, with the exhaustion of the sugar. The 100 grams of saccharose taking part in the fermentation yields 60 to 80 per cent. of lactic acid, 10 to 20 per cent. of acetic acid and 1 to 7 per cent. of alcohol, with traces of acetone and the higher alcohols. The acetic convertor is even more efficacious than the lactic, but the yield of acetic acid has not exceeded that of the ordinary acetic fermentation. The test amount, 100 grams, of saccharose gave 40 to 50 per cent. of acetic acid, 10 to 20 per cent. of lactic acid and 1 to 2 per cent. of acetone. It is believed that it will be possible to obtain acetic acid by this process without passing through the intermediate stage of alcohol.

Medical Mobilization and the War

Amendments Affecting Medical Officers

Amendments have been proposed in the Senate to the National Defense Act to the effect that members of the Medical Reserve Corps or contract surgeons on active duty for twelve years subsequent to 1898 shall be eligible to appointment as first lieutenant in the Medical Corps, subject to examination, and any officer who fails to pass the physical examination by reason of disability incurred in the service shall be retired with pay and allowance of first lieutenant of the Medical Corps.

Personnel of the Medical Department

For the week ending March 23, the personnel of the Medical Department of the Army included:

Medical Corps: 799, including 1 major-general, 66 colonels, 102 lieutenant-colonels, 177 majors, 2 captains and 451 lieutenants.

Medical Reserve Corps: 18,138, including 1,090 majors, 4,229 captains and 12,819 lieutenants. On active duty: 14,911, including 983 majors, 3,685 captains and 10,243 lieutenants.

Medical Corps, National Guard: 1,236, including 12 lieutenant-colonels, 257 majors, 151 captains and 816 lieutenants.

Medical Corps, National Army: 81, including 3 brigadier-generals, 12 colonels, 59 lieutenant-colonels and 7 majors.

The Dental Corps, 209; Dental Reserve Corps, 5,280, of whom 1,316 are on active duty; Dental Corps N. G., 259; Veterinary Corps, 24; Veterinary Reserve Corps, 1,425, of whom 806 are on active duty; Veterinary Corps N. G., 57; Veterinary Corps N. A., 297; Sanitary Corps, 990, and Ambulance Service, 142, constitute the remainder of the commissioned personnel.

The DISCHARGES in all branches of the service to date are:

Causes	Number			
	MRC	MC,NG	DC,NG	San C.
Physical disability	461	35	6	4
Inaptitude	180	10	0	1
Other branches of the service	377	18	2	42
Domestic troubles	30	0	0	1
Needed by the community	35	1	0	0
Deaths	42	3	0	0
Dismissals	0	2	0	0
Resignations	131	42	5	8
	1,256	111	13	56

Reconstruction Aids

Reconstruction hospitals for the training and reeducation of the wounded and crippled soldiers of the war will soon be established by the medical department of the Army. It is reported that there is now a demand for specially trained women to give remedial exercises and massage to returned soldiers. The members of this force will be called reconstruction aids, 100 of whom are said to be needed immediately, with many more in the near future. The Surgeon-General has announced regulations for the examination of applicants for these positions, who must be graduates of training schools for nurses and furnish one letter of recommendation from an orthopedic surgeon and another from the principal of a school who knows the applicant personally. The Surgeon-General refers women who wish to take this training to the following certified schools: American School of Physical Education, 44 Botolph street, Boston; Boston School of Physical Education, 105 South Huntington Avenue, Boston; Posse Normal School of Gymnastics, 779 Beacon Street, Boston; New Haven Normal School of Gymnastics, 1446 Chapel Street, New Haven, Conn.; Normal School of Physical Education, Battle Creek, Mich., and Reed College, Portland, Ore. The course of training comprises instruction in anatomy, physiology, personal hygiene, the theory of massage and remedial exercises, theory of bandaging, and practice in the last three subjects.

FROM AN M. R. C. OFFICER IN FRANCE

Somewhere in France, Feb. 26, 1918.

The censor permits me to state that I am in France, in the zone of the armies; that I am chief surgeon in a hospital attached to the X...... corps, Y...... army, in the Z...... sector. I shall try, in fear and trepidation, to convey to you the information that twelve of Our Boys—of whom two are officers—are at this moment sharing the benefits of this establishment with their French comrades. Mr. Censor may even allow me to state that the hospital grounds can still boast of artillery emplacements, trenches and entanglements, although the veterans of the French army are now busily removing these reminders of the terrific conflicts of 1914-1917; which fact, if you only stop to think of it, indicate to my mind that the general staff is not paying much attention to Hindenburg's recent boast that he would dine in Paris on April fool's day!

When I look back to the strenuous days of Fort Benjamin Harrison, and recall the "angor animi" which overwhelmed me when, as C. O. of my company, I shouted "right front in line" instead of "on right into line," thus scattering my men all over the railroad track and causing our esteemed instructor to yell "look at you, look at you; just like a flock of sheep"! I realize that the scene has shifted quite considerably and that other matters, equally vital, now occupy our thoughts!

AEROPLANE RAIDS

Everything is topsy-turvy; as I write in bed, a glorious full moon illuminates the country around me, but heavy black curtains over my window and a tightly closed door, prevent me from gazing at it, no lights being allowed to appear from the outside for fear of attracting the attention of an enemy night prowler of the air. "Damn the moon," remarked an officer to me, as we gazed skyward before retiring, "this means a visit from Fritz tonight."

A clear day means "good visibility" and, while I am strolling along the high road, enjoying the beautiful scenery, Fritz, sitting in the basket of his "sausage" stationary balloon back of yonder hill, is probably telephoning a Boche battery words to this effect: "Idiotic Yankee on high road; three thousand yards; give him hell"! Fortunately you hear the whizz of the coming shell, jump into the trench which borders the road and crouch low until the beastly thing has exploded. Other shells may follow the first one, or Fritz may only have wished to notify you that promenading along the high road was not a healthy occupation, and you retrace your steps in the trench until a turn of the road hides you from those invisible but all-seeing eyes.

Aeroplane bombs give you no warning; you hear the faint purring of the engine, several thousand feet above you, and recognize its nationality by . . . beg pardon, Mr. Censor, but the aeroplane itself is invisible! You take to the nearest shelter and trust that the bomb will not make a direct hit. A terrific "wrrang" loudly informs you that the bomb has touched ground and exploded. As aeroplanes travel rapidly, if the first bomb has fallen near you, you are perfectly safe and crawl out to take a look around; if the explosion is a distant one, you crouch and wait—perhaps for your turn to come!

Protection against shell fragments is easily obtained. Tiers of sand bags, baskets filled with earth or gravel or two parallel sets of chicken wire, 1 foot apart, strung around the hut or ward and filled in with earth, keep you perfectly safe. If the bomb should happen to hit the roof . . . that's another matter! Hospitals are now provided with bomb-proof dugouts and, if the alarm is sounded soon enough, patients and personnel can be placed in absolute safety, even against a direct hit.

A CAMOUFLAGED HOME

It is a long way from the "pup tent," which we were taught to put up or take down in three minutes and forty-five seconds, to the wooden huts in which the officers M. C. now live! Its roof and walls are camouflaged; double chicken wire and earth surround it; doors and windows are tightly closed and curtained at night, as long as any light is burning. In one corner is the cot, surrounded by a 3-foot wall of sand bags, giving one the illusion of a bath tub! You remove a few clothes—none when the moon is shining—take a running jump and clear the sand bags; excellent exercise just before retiring! Having accomplished this acrobatic feat, you place your gas mask and helmet where you can instantly grab them, test your flashlight to see if it has not "gone dead," pull the woolen "crusader's head gear" which loving fingers have knitted for you, over your head, and settle down to dream of enameled bath tubs with hot running water, Castile soap and Turkish towels! Instead of the rumble of the elevated train or the honk honk of the autos on the boulevard, the dull boom of heavy cannon, or short, angry bark of anti-aircraft guns, soothe you to sleep.

A REGIMENTAL AID POST

Let me try and picture to you a typical French regimental aid post, the only kind we shall have as long as trench warfare exists:

To reach it, you zigzag through an evacuation trench from 1 to 4 miles long, 7 feet deep and 4 wide, twisting from right to left until your head is dizzy and you have to lean against the earth, remove your helmet and mop your brow while your semicircular canals are readjusting themselves!

The bottom of the trench may be dry in places, if "duck-boards," drainage, soil and climate are all willing that it be so; more often than not, you flounder, slip and splash in the mud and water. Trench evacuation is computed on the basis of four stretcher-bearers per wounded, per kilometer, per hour, which gives one an exact idea of its difficulties. My sympathy and admiration go out to the brave and sturdy men who have to carry a wounded soldier through these mud holes; their work is herculean.

Relay stations are placed five hundred yards apart, in which one or more squads of stretcher-bearers are posted. The station is a dugout, from 10 to 20 feet below the surface of the ground, heated by a small wood-burning stove with a chimney running up the side of the stairway, and lighted by acetylene lamps. The stairway is 3 feet square and placed at an angle of 45 degrees, so that in descending or ascending, the steel helmet demonstrates its immense value, as it bumps against the supporting beams. To watch a loaded stretcher carried down at this perilous angle is a never to be forgotten sight. Should the stretcher bearers get caught in a barrage fire they take refuge, with their wounded, in the relay station.

The particular regimental aid post which I am going to try and describe, is built two stories deep, the first room 16 feet, the second 30 feet below the surface of the ground. Each room is 60 feet long, 18 wide and 7 feet high, securely walled and beamed and divided into three compartments by wooden partitions. The same standard type stairway connects the two rooms.

Behind the lower room runs a gallery 4 feet wide, 7 high and 500 yards long, which connects the aid station with the rest of the Troglodyte village. Over two thousand men live there underground, their health apparently none the worse for the change.

GAS ATTACKS

The upper stories are used as mess rooms, offices, store rooms, etc.; the lower ones as sleeping quarters for officers and men. At each end of the village, the underground gallery has a camouflaged exit, so that in case of a surprise attack at one end, officers and men can escape from the opposite side. Protecting all of the upper entrances are pyramids of sand bags, so that shell fragments cannot fly down the stairways. As a protection against gas attacks, each entrance has a stout sheet of canvas hanging in front of it, immediately behind which is a double door which fits snugly and closes accurately. Six feet down the stairs, a second canvas sheet is placed, and finally, another 6 feet further down a second door and third canvas sheet complete the antigas system. A gas shell can be recognized by the soft "psstt" which it makes when it explodes, very different from the high-explosive "bang."

At the first gas-shell explosion the guard sounds a siren, horn or wooden rattle. Gas masks are immediately applied by officers and men, and every stairway is closed. A hospital corps man seizes a large sprayer (similar to the ones used by fruit growers), filled with a solution of sodium or potassium bicarbonate, and rapidly sprays all three of the canvas sheets. Having done so, he stands between the second door and second sheet and continues to spray the second canvas as long as the attack lasts. The sheet is kept moist but not dripping. At the same time chlorinated lime powder is sprinkled on the floors, especially at the bottom of the stairways. Each of the lower rooms has, at one end, a ventilating shaft, 6 inches square, extending vertically from the ceiling and ending 1 foot above the surface of the earth. A tin cap on a spring hinge enables the shaft to be closed during a gas attack. Attached to the inner side of the cap is a long string which passes down the air shaft into the room. At the first alarm the soldier nearest the shaft has orders to pull the string taut and fasten it to a convenient nail.

OPERATING ROOMS

The operating and dressing room, 16 by 10 by 7 feet, is located immediately in front of the stairway. It is amply lighted by four acetylene lamps and well ventilated. The operating table is a simple but adequate one, and the field instrument case contains all of the necessary instruments for first-aid surgery of the ordinary type. Sterilizing is done by boiling over a [illegible] Primus lamp. The surgeon in charge, a captain, had trained one of his orderlies to give ether or ethyl chlorid anesthesia, and a second orderly acted as assistant.

As in all sanitary formations in the zone of the advance, the amount of operative work depends on the activity of the sector. In periods of ordinary "strafing," thorough excision of lacerated tissues is done; fractures are set and immobilized with traction; hemorrhages are checked by direct ligation of the artery in the wound, and shock is treated by giving hot drinks, lowering the patient's head and placing him in a "cellule chauffante," a hot chamber improvised by means of blankets and an alcohol lamp, hot air being conveyed under the blanket through a metal or wooden chimney.

Sterilization of the wound after excision en masse of all lacerated tissues (débridement) is obtained by means of ether in all deep lacerated wounds or perforating wounds; by tincture of iodin in superficial wounds. The first injection of 500 units of antitetanic serum is given, with morphin whenever indicated. No attempt is made to perform esquillectomy (removal of loose bone fragments), or to remove shell fragments unless they appear within the wound and can be easily extracted. Tracheotomies for manifest edema of the glottis are performed here, but no intracranial, intrathoracic or intra-abdominal surgery is attempted. In other words, the surgeon aims to render a majority of the simpler wounds aseptic, but he, very properly, makes no attempt to do any reparative work amid surroundings which are manifestly inadequate for such procedures.

During active fighting, when as many as two hundred cots are occupied by wounded men, nothing is done except to cleanse the wound with ether and apply a sterile dressing. Antitetanic serum and morphin are given, the former in all cases, the latter when deemed necessary. Put tersely, the regimental surgeon does as much as he can under the circumstances. After almost four years of war, the French sanitary service has learned that a service which lacks elasticity and quick adaptability, is bound to fail. Given the proper staff and personnel, a certain latitude must be allowed each regimental surgeon in order that he may be able to render the best service to the greatest number of wounded in the shortest space of time.

NEWS OF THE CANTONMENTS

Twenty-Eighth Division, Camp Hancock, Augusta, Ga.

March 16, 1918.

Lieuts. Hendricks and Good, M. C., and Lieuts. Fink and Shannon, D. C., have been promoted to the grade of captain.

The family of Major Thompson, surgeon to the One Hundred and Ninth Field Artillery, is staying at "The Lenwood."

The large base hospital at Camp Hancock has received an additional quota of trained nurses, and an extra building has been erected to accommodate them.

Thirty-First Division, Camp Wheeler, Macon, Ga.

March 22, 1918.

Camp Wheeler has passed through a severe winter with a high sick rate, but has survived, and is now doing better. The sick rate is moderate, considering that the Thirty-First Division is now more than half draft men. Measles, mumps and pneumonia have practically disappeared. Meningitis was never a menace. Venereal disease has increased during the last month. In spite of a strenuous campaign against immoral houses in Macon, the number of prostitutes has increased. Lieutenant Miner, who works with the Fosdick Commission, has succeeded in securing the conviction of some prominent offenders. Keepers of so-called hotels, really houses of prostitution, have been prosecuted under the 5-mile law, and brought to justice.

Orders for inspection tours by officers of the base hospital have resulted in visits to the neighboring camps by Major Lund, and visits to this camp by Major Halsted of Camp Hancock, and Major Babcock of Fort McPherson.

Thirty-five officers from the base hospital have been selected for service abroad. It is not known how soon they will go, but it is said that there was a scramble to get on the list. eutenant-Colonel Keenan of the sanitary train was at horpe during the week. Major Patterson accompanied al detachment to Camp Merritt. tenants Bertolet and Leavett have been transferred e sanitary train to the base hospital.

The long awaited examination for promotion of first lieutenants, M. C. of the National Guard, took place, March 12 and 13. All lieutenants with one year's service were examined. A similar examination for dental surgeon will take place at once.

Major R. C. Turck has been made sanitary inspector of the camp. Major Loren Greene is now sanitary inspector of the Thirty-First Division.

Lieut. William A. McKeever, M. R. C., has been discharged on account of physical disability, and has gone to his home in Philadelphia.

A beginning has been made in the training of convalescents and defectives, in the convalescents at the base hospital. As the war goes on, and the need for first class men becomes greater, this work will assume more and more importance. Men who were or have become unfit for first line duties must be made fit for such other duties as they can perform. Many men not competent for the infantry or artillery can be used in the Quartermaster Corps, the Veterinary Corps, the Ordnance Corps, the Medical Corps and in other places.

Major Turck is sick in the base hospital, but is expected to be out soon.

Eight new ward buildings, of two wards each, are being constructed at the base hospital. They will furnish accommodations for 600 patients.

Two hundred negro draft men have arrived for sanitary work about the camp. They will be of great assistance in drainage and other work. The drainage of the swamp areas within the camp is going on rapidly under the direction of Major Turck and Captain Mitchell. Swamps in Camp Wheeler will soon be a thing of the past. It is hoped to have the work completed before the real mosquito season.

Thirty-Third Division, Camp Logan, Houston, Texas

March 18, 1918.

The wisdom of selecting camps in the more southerly states for most of the training activities of the new Army is becoming more apparent every day. We have had scarcely a day during the winter in which some outdoor work could not be carried on. Even on the windiest and coldest days we see aeroplanes flying as usual, and the absence of snow and wind has contributed to render the drill, trench work, etc., possible at all times.

PERSONAL

Major J. M. Willis, commanding officer of the base hospital, has been promoted to the rank of Lieutenant-Colonel, Medical Corps, National Army.

Major Harry D. Orr, recently director of ambulances, Thirty-Third Division, has received a similar promotion and been placed in command of the Thirty-Third Division sanitary trains.

The visiting English and French officers have given us all a much more intimate knowledge of what may be expected in France than we could possibly attain from other sources, and they are very closely followed by our officers who are receiving instructions from them.

Major J. H. Blackburn, M. R. C., chief of surgery in our base hospital, has just returned from a tour of the hospitals at Camp Beauregard, Alexandria, La., Camp Pike, Little Rock, Ark., and Camp Bowie, Fort Worth, Texas.

Major O. H. Campbell, M. R. C., of Camp McArthur, Waco, Texas, has visited this hospital during the present week, and Major J. N. Hall, M. R. C., of our hospital is to visit three of the neighboring cantonments shortly. This is all in pursuance of the plan to have the chiefs of departments compare notes with others in similar work for the benefit of the service.

Colonel Willis is soon to make a similar tour for conference with other commanding officers.

SURGICAL WORK

Major Blackburn furnishes the following data as to the surgical work in the base hospital:

Personnel of the surgical division, base hospital staff: Major J. H. Blackburn, M. R. C., chief; Capt. W. F. McManus, M. R. C.; Capt. C. H. Parks, M. R. C.; Capt. S. M. Strong, M. R. C.; Capt. W. B. Carroll, M. R. C., orthopedic department; First Lieut. F. L. Patterson, M. R. C., brain surgery; Capt. F. M. Barnes, M. R. C., oral and plastic surgery; First Lieut. W. P. Barton, M. R. C.; First Lieut. J. G. Murfin, M. R. C.; First Lieut. F. N. Haggard, M. R. C.; First Lieut.

O. C. Brown, M. C. N. G.; First Lieut. S. F. Weitzner, M. R. C., roentgenologist.

During the period from Sept. 15, 1917, to Jan. 31, 1918, there were discharged from the service, through the base hospital, 1,748 patients. Those suffering from disabilities which may be classified as surgical were 639 in number, about 36 per cent. Classified as to anatomic regions there were 199 cases involving the feet and legs, including flatfoot (170 cases), hallux valgus, talipes varus, genu valgum and loose bodies in the knee joint. During this time four men with hallux valgus were operated on making a total of 203 cases. There were fifty-four cases of diseases of the joints, the larger percentage of these being in the lower extremities and including arthritis, ostearthritis, synovitis, ankylosis, dislocations and subluxations.

The diseases of the bones not classified above were twenty-eight in number, and included periostitis, osteomyelitis, necrosis, fractures and exostoses. There were ninety-three deformities of varying character in addition to these of sufficient degree to interfere with the work of the patients as soldiers. A large percentage of these involved the lower extremities; thus we find practically 50 per cent. of the surgical cases of such character and so situated as to interfere with locomotion.

In addition to the deformities above mentioned, there were seven deformities of the spine, including scoliosis, kyphosis, spondylitis and torticollis.

Aside from the flatfoot cases, the largest single class was found to be goiters, of which there were 151. In this class were included simple cystic goiters which were large enough to interfere mechanically on exertion. There were a number of classical cases of exophthalmic goiter in which there were exophthalmos, enlargement of the thyroid and tachycardia. In addition there were a large number of men who under the stress of Army life had developed a tachycardia with a pounding impulse over the precordia, a marked tremor, and very poor cardiac response after exercise. Some of these had slight enlargement or slight exophthalmos, and in some neither of these signs was present.

Fifty-nine hernia patients were discharged. In addition there were ninety-two patients operated on, making a total of 151 cases of hernia.

Diseases of the vascular system were 20 in number, and included varicose veins of the legs, varicocele, phlebitis and hemorrhoids. There were 106 men with hemorrhoids, varicocele and varicose veins operated on, making a total of 126 cases.

There were nine cases of diseases of the testicles, including atrophy, nondescent, orchitis and hydrocele.

Other conditions found in small numbers include peritoneal adhesions producing pain in the abdomen, ischiorectal abscess, congenital absence of the pectoral portion of the pectoralis major muscle, and dyspituitarism with feminine type of development. There were also three cases of myositis of the forearm, two being typical cases of Volkmann's contracture, and the third involving the extensor muscles of the forearm rather than the flexors.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

March 25, 1918.

CONVALESCENT INFIRMARY

Conservation of man power will be one of the principal objects of the convalescing infirmary of the base hospital. Work on the twelve new two-story buildings for this institution was started this morning. They will provide accommodations for 800, increasing the capacity of the hospital to 2,000 patients. Lieut.-Col. Will L. Pyles, superintendent, has received word from Surgeon-General Gorgas, at Washington, D. C., that the additional twelve regular wards for the hospital, which for a time were contemplated, will not be erected. The new buildings are being put up on the west end of the main plant, on the south side of Washington Avenue, between Lincoln Avenue and the Preston-Street Road. They will cost approximately $360,000.

The convalescing infirmary will serve three purposes. Convalescents will be treated there, certain patients will be kept under observation, and the place will be a reconstruction camp for selects suffering from minor physical defects. The infirmary will cover a 10-acre tract. In the center will be a recreation building of the Red Cross. The wards will be connected by long corridors with the main hospital so that the patients may go to the mess hall without exposing themselves to inclement weather.

Drafted men having flat feet, ruptures, or other defects will be put in the infirmary with a view to remedying their trouble and making ablebodied men of them for active military service. It is said that a number of recruits have been discharged for physical disqualifications who could have been saved for Uncle Sam had they been subjected to special treatment.

CONTAGIOUS DISEASES AND FACE MASKS

A new system has been inaugurated in the handling of soldiers suffering from contagious diseases in the effort to avert epidemics. Masks are worn by patients having respiratory ailments during their removals from the regimental infirmaries or barracks to the base hospital, and while they are in the receiving ward. This prevents others with whom they come in contact from breathing the germs. Separate ambulances are used in conveying such patients.

Different entrances are used in admitting them at the hospital and they are segregated from the moment they are classed as "suspects" of communicable diseases by the medical officers of their respective organizations. This is expected to improve the general health conditions at Camp Zachary Taylor.

PASSES TO CAMP

Orders regarding visitors at Camp Zachary Taylor practically close the cantonment to the public with the exception of the regularly established visiting periods, Wednesday and Saturday afternoons and Sundays. Only civilians having passes will be permitted within the reservation and no passes will be issued other than to persons having business dealings with the government.

Passes will not be given to women, the order directs. Persons having relatives or friends at the camp may call at the base hospital or the hostess house, but they cannot enter the grounds except during visiting hours. However, they may call by telephone from these stations to the commander of the unit in which the soldier they are anxious to see is serving, and he may be sent to the hospital or hostess house to meet them.

BASE HOSPITAL

The sick report of Camp Zachary Taylor at the present time is higher than it was during the bad weather. It is stated the reason for this is that a soldier is not discharged from the base hospital until he is able to go from the hospital to the drill field. The sick report shows more than 1,700. The report has been boosted considerably since the new draft arrived on account of many diseases being found among them which under the new regulations hold them in the Army. Three hundred are quarantined with measles, 78 have pneumonia, 16 erysipelas, 2 meningitis, 7 chickenpox and 1 smallpox.

PERSONALS

First Lieut. Val E. Miltenberger reported in compliance with War Department orders and was assigned to duty as sanitary inspector of the Eighty-Fourth Division, which place was made vacant when Major Luther R. Poust was made camp sanitary officer and assistant of the division surgeon, Lieut.-Col. John H. Allen. Major Poust is in the East, having been granted a leave of absence. Col. Albert M. Truby, of the Surgeon-General's Office, who is on a tour of inspection of the cantonments throughout the country, is at Camp Zachary Taylor.

Major Walter Hamburger of the base hospital has been ordered to the following camps to confer with the medical officers: Major Alfred Friedlander, M. R. C., Camp Sherman, Chillicothe, Ohio; Major Ernest E. Irons, M. R. C., Camp Custer, Battle Creek, Mich.; Major Joseph A. Capps, M. R. C., Camp Grant, Rockford, Ill.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending
March 15, 1918

1. ANNUAL ADMISSION RATE PER 1,000 (DISEASE ONLY)

All Troops	[illegible]
National Guard Camps	975.1
National Army Camps	[illegible]
Regular Army	[illegible]

2. NONEFFECTIVE RATE PER 1,000 ON DAY OF REPORT:

All Troops	50.6
National Guard Camps	40.2
National Army Camps	58.8
Regular Army	44.2

3. ANNUAL DEATH RATE PER 1,000 (DISEASE ONLY):

All Troops	7.5
National Guard Camps	4.2
National Army Camps	9.1
Regular Army	7.9

ORDERS TO OFFICERS OF THE MEDICAL CORPS

To New York City, Hoboken, N. J., Camp Merritt, N. J., for duty, and on completion *to his proper station,* Brig.-Gen. CHARLES RICHARD.

To Allentown, Pa., for inspection, and on completion *to his proper station,* Col. THEODORE C. LYSTER.

To Baltimore, Md., for inspection, and on completion *to his proper station,* Col. WESTON P. CHAMBERLAIN.

To Fort Oglethorpe for inspection, and on completion *to his proper station,* Col. ELLIOTT C. BRACKETT.

To Camp Kearny, Linda Vista, Calif.; *Camp Fremont,* Pala Alto, Calif., for conference, and on completion *to his proper station,* from Camp Cody, Lieut.-Col. JACOB M. COFFIN.

To Mineola, Long Island, N. Y., for inspection, and on completion *to his proper station,* Lieut.-Col. PEARCE BAILEY.

To Waynesville, N. C., for duty, and on completion *to his proper station,* Lieut.-Col. EARL W. BRUNS.

To Army Medical School for duty, Major CLARENCE L. COLE.

To Camp Gordon, Atlanta, Ga., for duty, from Camp McClellan, Major LUTHER H. REICHLEDERFER.

To Fort Riley for duty, from Camp Doniphan, Major WILLIAM S. LAWRENCE. For instruction, having passed the preliminary examination for appointment in the Medical Corps, Lieut. ROY M. COX.

To Metuchen, N. J., for duty, from Allentown, Major CHARLES C. HILLMAN.

To Camp Greene, Charlotte, N. C., base hospital, *from Camp Greene,* Lieut. PAUL B. STRAIT.

To Columbus Barracks, Ohio, for duty, from Philadelphia, Lieut. WILLIAM L. STRANES.

To Newport News, Va., for temporary duty, from Army Medical School, Lieut. ROYAL K. STACEY.

Resignation of Lieut. CHESTER C. BULLARD is accepted.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Camp Joseph E. Johnston, Jacksonville, Fla., for duty, from Fort Oglethorpe, Lieut. ALFRED C. SMITH, Shawmut.

To Fort McHenry, Md., for duty, Lieut. HARRY C. EDMUNDSON, Birmingham.

To Fort Oglethorpe for instruction, Capt. HUGH BOYD, Scottsboro; Lieuts. ARTHUR JOHNSON, Clanton; ROBERT H. COKER, East Tallassee; THEODORE M. BLAKE, Fruitdale; JOHN P. SCALES, Livingston; *from Camp Beauregard, Lieut. FLOYD L. ABERNETHY,* Flomaton; from Camp Sherman, Lieut. ALBERT D. McFADDEN, Ariton.

To Hoboken, N. J., for duty, from Fort Oglethorpe, Lieut. JAMES O. MORGAN, Piedmont.

To Laurel, Md., for duty, from Fort Oglethorpe, Lieut. JAMES F. BEAN, *Brundidge.*

To Los Angeles, Calif., for duty, from Camp Kearny, Lieut. GUY E. STEWART, Attalla.

To New Orleans, La., for instruction, and on completion *to Camp Shelby,* Hattiesburg, Miss., base hospital, Lieut. JOSEPH A. MAXWELL, Tuscaloosa.

To Newport News, Va., for duty, from *Fort Oglethorpe,* Capt. THOMAS H. STREET, Alexander City.

To New York City for instruction, from Camp Bowie, Lieut. CHARLTON S. HARRIS, Birmingham.

To Walter Reed General Hospital, Takoma Park, D. C., for duty, *from* Newport News, Major EUGENE DuB. BONDURANT, Mobile. For duty, on completion of instruction at Philadelphia, Lieut. LONNIE W. GROVE, Tuscaloosa.

Arizona

To Fort Riley for instruction, Lieuts. FRED O. LION, Clifton; JEROME McM. LEONARD, *Douglas;* THOMAS J. BOULDIN, St. Johns; ROY R. KNOTTS, Yuma.

Arkansas

To Army Medical School for instruction, Lieuts. JAMES J. ROCK, Iowa City; AMOS E. ROBINSON, Leachville.

To Camp Logan, Houston, Texas, for duty, from Camp Joseph E. Johnston, Capt. EDWIN BLEDSOE, Little Rock.

To Camp Pike, Little Rock, Ark., base hospital, from Camp Pike, Lieut. FRANK L. CASTLEBERRY, Paragould.

To Dansville, N. Y., for temporary duty, *from Fort Oglethorpe,* Lieut. CARL S. BUNGART, *Fort Smith.*

To Fort McPherson, Ga., for duty, *Major* WILLIAM A. SNODGRASS, Little Rock.

To Fort Oglethorpe for instruction, Lieuts. HERBERT S. WATSON, Earle; FRED R. MORROW, Green Forest; GROVER C. WEBB, Hector; CHARLES E. BYLER, Lepanto; LOUIS D. H. DONALDSON, Parma; MOSES C. HUGHEY, Rector.

To Houston, Texas, Signal Corps Aviation School, for duty, from Fort Riley, Lieut. NICHOLAS W. RIEGLER, Little Rock.

To Newport News, Va., for duty, from Fort Oglethorpe, Capt. ALFRED C. HEARN, Arkadelphia.

California

To Camp Fremont, Palo Alto, Calif., base hospital, *Capt.* JAMES T. DISHER, Los Angeles.

To Camp Kearny, Linda Vista, Calif., for duty, *from* Camp Kearny, Capt. LEWIS D. REMINGTON, Monrovia.

To Fort Des Moines, for duty, from Camp *Kearny, Capt.* WILLIAM J. CHAMBERS, Los Angeles.

To Fort Riley for instruction, Lieut. EARL L. LUPTON, Los Angeles.

To Mineola, Long Island, N. Y., Hazelhurst Field, for duty, from San Francisco, Capt. HENRY W. HORN, San Francisco.

To Newport News, Va., for *temporary* duty, from *Fort Riley,* Capt. WILLIAM W. ROBLEE, Riverside.

To San Diego, Calif., Rockwell Field, Aviation Section Signal Corps, for duty, Lieuts. FRANCIS X. AMMAN, Jr.; MILTON D. W. JEFFS, Los Angeles.

To San Francisco, Calif., for duty, Capt. FRANK L. DOANE, Red Bluff.

To Western Department for duty, Lieut. LLOYD B. CROW, San Francisco.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. ERNEST P. WOODWARD, Los Angeles.

Canal Zone

To Allentown, Pa., Concentration Camp, for duty, from Fort Riley, Major THOMAS J. LEARY, Cristobal.

Colorado

To Camp Dix, Wrightstown, N. J., for duty, from Fort Riley, Lieut. LOUIS O. BOLTON, Cedaredge.

To Camp Dodge, Des Moines, Iowa, for duty, from Camp Dodge, Lieut. PHILIP WORK, Pueblo.

To Camp Logan, Houston, Texas, base hospital, from Philadelphia, Lieut. TOM R. KNOWLES, Colorado Springs.

To Fort Oglethorpe for instruction, from Camp Sherman, Lieut. ORION A. GRANTHAM, Johnstown.

To Fort Riley for instruction, Lieut. OSCAR A. DUNCAN, Crawford.

To Pittsburgh, Pa., for instruction, and on completion *to Camp Sevier*, Greenville, S. C., base hospital, from Fort Riley, Lieut. AUGUSTINE S. CECCHINI, Denver.

Connecticut

To Army Medical School as tuberculosis instructor, from Camp Grant, Capt. CHARLES H. TURKINGTON, Fitchfield. For instruction, Lieuts. RALPH L. WHITE, New Canaan; FRED W. COMSTOCK, BURTON E. LOVESEY, New Haven; JOHN W. CALLAHAN, Norwich.

To Camp Gordon, Atlanta, Ga.; *Camp Wheeler*, Macon, Ga.; *Camp Hancock*, Augusta, Ga.; *Camp Jackson*, Columbia, S. C., base hospitals, and on completion *to his proper station*, from Camp Sevier, Major JOHN S. DYE, Waterbury.

To Camp Wheeler, Macon, Ga., for temporary duty, and on completion *to Camp Shelby*, Hattiesburg, Miss., for duty, from Camp Bowie, Capt. OTTO G. WIEDMAN, Hartford.

To Fort Oglethorpe for duty, from Fort Hamilton, Lieut. LEONARD J. LOEWE, Higganum. For instruction, Lieut. SIMON B. KLEINER, New Haven.

To Newport News, Va., for duty, from Fort Oglethorpe, Lieuts. SAMUEL E. WITT, Chesterfield; JAMES P. McMANUS, Hartford.

To New York City, Neurological Institute, for intensive training, Capt. WILLIAM R. MILLER, Southington. *Bellevue Hospital*, for instruction, and on completion *to Camp Upton*, Long Island, N. Y., base hospital, Lieut. ANDREW J. JACKSON, Waterbury. On completion *to Fort McPherson, Ga.*, for temporary duty, Lieut. RAYMOND H. RYDER, Waterbury.

To Rockefeller Institute for instruction, and on completion *to Williamsbridge, N. Y.*, for temporary duty, Capt. FRITZ C. HYDE, Greenwich.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. NAPOLEON B. LEWIS, Norwich.

Delaware

To Cape May, N. J., for temporary duty, from Philadelphia, Lieut. EDWIN H. LENDERMAN, Wilmington.

To Fort Oglethorpe for instruction, Lieuts. JAY H. McCLELLAN, Pinehurst; HENRY R. KRITZER, Wilmington.

District of Columbia

To Camp Dix, Wrightstown, N. J., for duty, and on completion *to his proper station*, Major SCOTT D. BRECKENRIDGE, Washington.

To Camp Meade, Annapolis Junction, Md., for duty, from Camp Meade, Lieut. HARRY C. KING, Washington.

To Fort Riley for instruction, Capt. OTTO L. MUENCH, Washington.

To New York City, Neurological Institute, for instruction, and on completion *to Camp Meigs*, Washington, Major HARRY H. KERR, Washington. Bellevue Hospital, for instruction, and on completion *to Camp Meade*, Annapolis Junction, Md., base hospital, from Camp Wadsworth, Lieut. SIDNEY C. COUSINS, Washington. From Fort Oglethorpe, Lieut. PAUL S. PUTZKI, Washington.

Florida

To Camp Wheeler, Macon, Ga.; *Camp Gordon*, Atlanta, Ga.; *Camp Hancock*, Augusta, Ga.; *Camp Jackson*, Columbia, S. C., base hospitals, and on completion *to his proper station*, from Camp Joseph E. Johnston, Major HARRY A. PEYTON, Jacksonville.

To Fort Oglethorpe for instruction, from Camp Meade, Major HERRMAN H. HARRIS, Jacksonville. For instruction, Lieuts. JOHN D. GABLE, Bonifay; RALPH D. MURPHY, St. Petersburg.

Georgia

To Army Medical School for instruction, Lieuts. DANIEL O. KELLEY, Lawrenceville; THOMAS B. KING, Sandersville.

To Atlanta, Ga., School of Technology, for duty, from Atlanta, Capt. JOHN H. HALL, Lieut. ERNEST S. COLVIN, Atlanta.

To Camp Hancock, Augusta, Ga., for duty, from Fort Oglethorpe, JAMES Q. FOLMER, Atlanta.

To Camp Sherman, Chillicothe, Ohio, for duty, from Fort Oglethorpe, Lieut. STEPHEN T. BROWN, Atlanta.

To Fort Oglethorpe for instruction, Lieuts. HOMER L. REDD, Atlanta; WILLIAM O. SHEPARD, Blakely; RALPH J. GREENE, Bluffton; HOMER BOWEN, Claxton; THOMAS R. MOYE, Ebbeville; REUBEN T. CAMP, Fairburn; HAMPTON M. BARKER, KARL H. BARTH, Flintstone; CLEVELAND D. WHELCHEL, Gainesville; LOUIS B. ROYAL, Girard; WALLACE H. CLARK, La Grane; MELL AYCOCK, Monroe; FRANCIS M. BURKHALTER, Nashville; EVERETT STOTHART, Savannah; MASTIN L. PIPES, Ty Ty; CLAUDE H. SULLIVAN, Zebulan; from Camp Beauregard, RALPH E. HAMILTON, Douglasville.

To Hoboken, N. J., for duty, from Fort Oglethorpe, Lieut. HORACE F. STILTNER, Chickamauga.

To Newport News, Va., for duty, from Fort Oglethorpe, Lieuts. ALVAH W. WHITE, Box Springs; WILBUR M. SCOTT, Devereaux.

To Pittsburgh, Pa., for instruction, and on completion *to Camp Zachary Taylor*, Louisville, Ky., base hospital, from Fort Oglethorpe, Lieut. PAUL P. LANE, Waycross.

To Rochester, Minn., for instruction, and on completion *to his proper station*, from Fort Oglethorpe, Lieut. JOHN A. WHITE, Albany.

To West Point, Miss., for duty, from Fort Oglethorpe, Lieut. ERNEST R. HARRIS, Bethlehem.

To Williamsbridge, N. Y., for duty, from Fort Oglethorpe, Capt. WILLIAM C. HUMPHRIES, Acworth.

To the inactive list, from Atlanta, Major WILLIAM C. LYLE, Augusta.

Honorably discharged, Lieut. EUGENE THOMPSON, Lumber City.

Idaho

To Army Medical School for instruction, Lieut. SIMON HOPPER, Cambridge.

To Philadelphia, Pa., University Hospital, for instruction, and on completion *to Camp Dix*, Wrightstown, N. J., base hospital, from Fort Oglethorpe, Lieut. ELTON B. ROGERS, Winchester.

Illinois

To Army Medical School for instruction, Lieuts. RICHARD F. GREENING, FRED M. SMITH, Chicago; BRUCE A. HARRISON, Colchester; BENJAMIN H. HUGGINS, Evanston; SAMUEL M. HUBBARD, Ridgefarm; HENRY F. HOESLEY, Woodstock.

To Allentown, Pa., Concentration Camp, for duty, from Philadelphia, Lieut. EVERETT P. COLEMAN, Canton.

To Camp Bowie, Fort Worth, Texas, for duty, from Camp Bowie, Lieut. CHARLES W. MONROE, Arthur.

To Camp Cody, Deming, N. M., for duty, from Fort Riley, Lieuts. JESSE H. ROTH, Kankakee; JAMES T. BREAKEY, Mason.

To Camp Custer, Battle Creek, Mich., as tuberculosis specialist, from Fort Oglethorpe, Lieut. EDWARD BUCKMAN, Chicago.

To Camp Devens, Ayers, Mass., base hospital, from New York City, Capt. THOMAS W. MORGAN, Virden.

To Camp Dodge, Des Moines, Iowa, base hospital, Capt. DUNCAN B. McEACHERN, Chicago.

To Camp Doniphan, Fort Sill, Okla.; *Camp Bowie*, Fort Worth, Texas, and *Fort Riley*, for conference, and on completion *to his proper station*, from Camp Dodge, Major JOSEPH L. MILLER, Chicago.

To Camp Jackson, Columbia, S. C., base hospital, Lieut. WILLIAM T. ELLIOTT, Chicago.

To Camp Logan, Houston, Texas, for duty, from Fort Riley, Lieut. WALTER C. BISSON, Charleston.

To Camp McClellan, Anniston, Ala., base hospital, from Camp McClellan, Lieut. WALTER S. CONN, Naperville.

To Camp Meade, Annapolis Junction, Md., base hospital; on completion of instruction at Philadelphia, Capt. FRANK W. BRODRICK, Sterling.

To Camp Sheridan, Montgomery, Ala., base hospital, from Camp Sheridan, Capt. GEORGE C. SHOCKEY, Melrose Park.

To Camp Sherman, Chillicothe, Ohio; *Camp Zachary Taylor*, Louisville, Ky.; *Camp Custer*, Battle Creek, Mich., base hospitals, and on completion *to his proper station*, from Camp Grant, Major JOSEPH A. CAPPS, Chicago. Base hospital, from Philadelphia, Capt. ROBERT A. NOBLE, Bloomington. For duty, from Fort Oglethorpe, Lieut. ALEXANDER W. BURKE, Chicago.

To Army Medical School for instruction, Lieut. LUTHER J. CALAHAN, Manchester Centre.

To Camp Hancock, Augusta, Ga., for duty, from Fort Oglethorpe, Lieut. FRANK H. EVERETT, Castleton.

To Fort Oglethorpe for instruction, Capt. NATHAN R. CALDWELL, Graton; Lieuts. JAMES L. LOVEJOY, Manchester Depot; WILLIAM A. FLOOD, North Bennington; ROWLEY S. FLAGG, North Troy; BERN D. COLBY, Sudbury; JOHN N. CAISSE, Swanton; SHERMAN A. COOTEY, Wallingford.

To New York City, Bellevue Hospital, for instruction, and on completion *to Camp Upton*, Long Island, N. Y., base hospital, from Fort Oglethorpe, Lieut. GEORGE C. RUBLEE, Hardwick.

Virginia

To Army Medical School for instruction, Lieut. MERWIN B. MOORE, Raven.

To Camp Lee, Petersburg, Va., base hospital, from Fort Monroe, Major WILLIAM L. PEPLE, Richmond.

To Fort Monroe, Va., Aviation Section Signal Corps, from Richmond, Capt. WILLIAM W. GILL, Richmond.

To Fort Oglethorpe for instruction, Lieuts. WILLIAMSON C. WELBURN, Ballston; CHARLES B. FUGATE, Clinchport; ALFRED B. GREINER, Rural Retreat.

To Fort Ontario, N. Y., for temporary duty, Capt. GEORGE M. MAXWELL, Roanoke.

To Laurel, Md., for duty, from Fort Oglethorpe, Lieut. WHITFIELD P. DAVIS, Galax.

To Newport News, Va., for duty, from Fort Oglethorpe, Lieuts. EARLY B. DOVELL, Hillsboro; CHARLES E. DYER, Pulaski.

To New York City, Bellevue Hospital, for instruction, and on completion *to Camp Dix*, Wrightstown, N. J., base hospital, from Fort Oglethorpe, Capt. EDWARD H. MILLER, Jr., Danville. On completion *to Camp Meade*, Annapolis Junction, Md., base hospital, from Fort Oglethorpe, Lieut. STEPHEN R. DONOHOE, Jr., Norfolk.

To Rockefeller Institute for instruction and on completion *to Fort McPherson, Ga.*, for temporary duty, Capt. RICHARD P. BELL, Staunton. For instruction in laboratory work and on completion *to Army Medical School*, for duty, Lieut. ALBERT P. TRAYNAM, Richmond.

Washington

To Camp Travis, Fort Sam Houston, Texas, for duty, from Camp Travis, Capt. EDWARD A. RICH, Tacoma.

To Fort Sam Houston, Texas, for duty, from Fort Riley, Lieut. JO B. BLAIR, Vancouver.

To New York City, Cornell Medical Hospital, for instruction, from Fort Riley, Lieut. HAROLD B. THOMPSON, Seattle.

To Philadelphia, Pa., for instruction, and on completion *to Fort Riley* for temporary duty, from Camp Meade, Capt. JAMES G. MATTHEWS, Spokane.

To Western Department for duty, Lieuts. RAY SCHUTT, Bremerton; HARRY W. SHRYOCK, Sumas; WILLIAM W. WICK, Summer.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. CHARLES F. ENGELS, Seattle.

West Virginia

To Belleville, Ill., Signal Corps Aviation School, for duty, from Fort Oglethorpe, Lieut. WILLIAM P. SAMMONS, Cameron.

To Camp Hancock, Augusta, Ga., for duty, from Fort Oglethorpe, Lieut. MARK E. CALDWELL, Clendenin.

To Fort Oglethorpe for instruction, Capt. PATRICK L. GORDON, Charleston; Lieuts. FINLY K. VASS, Cassaway; HENRY G. BIELER, Charleston; RUFUS M. MUSICK, Gilbert; CHARLES P. S. FORD, EDWARD G. McCLEES, Hansford; WILLIAM C. MAYS, Sharon.

To New Orleans, La., for instruction and on completion *to Camp Shelby,* Hattiesburg, Miss., base hospital, from Jackson Barracks, Lieut. LATIMER P. JONES, Pennsboro.

Wisconsin

To Americus, Ga., for duty, from Fort Oglethorpe, Lieut. JOSEPH J. FRANCE, Milwaukee.

To Camp Bowie, Fort Worth, Texas, for duty, from Camp Bowie, Lieut. HENRY A. HALSEY, Hiles.

To Camp Cody, Deming, N. M.; *Camp Doniphan,* Fort Sill, Okla.; *Camp Bowie,* Fort Worth, Texas; *Camp Travis,* Fort Sam Houston, Texas, base hospitals, and on completion *to his proper station,* from Camp Kearny, Major JOHN R. McDILL, Milwaukee.

To Camp Dodge, Des Moines, Iowa, base hospital, Lieut. PERCY R. PIERSON, Readstown.

To Camp Taliaferro, Fort Worth, Texas, for duty, from Fort Riley, Lieut. JAMES R. HARVEY, Footville.

To Dallas, Texas, for duty, from Fort Riley, Capt. CLIFFORD W. ANDREWS, Waupaca.

To Fort Oglethorpe for instruction, Capts. WILLIAM HECKER, Beloit; BENJAMIN F. HOYT, South Kaukaua; from Pittsburgh, Capt. GENTZ PERRY, Amery.

To Fort Riley for duty, from Fort Riley, Lieut. EDWIN H. FEDEMAN, Montello. For instruction, Lieut. FREDERICK J. KORTHALS, Milwaukee.

To Fort Sam Houston, Texas, for duty, from Fort Riley, Lieut. WILLIAM F. WEINGART, Milwaukee.

To Houston, Texas, Signal Corps Aviation School, for duty from Fort Riley, Capt. PATRICK R. MINAHAN, Fond du Lac; Lieut. WILLIAM E. BUCKLEY, Hartford.

To Rochester, Minn., Mayo Clinic, for instruction, and on completion *to Camp Custer,* Battle Creek, Mich., base hospital, from Camp Grant, Capt. GEORGE SENN, Green Bay.

Honorably discharged on account of physical disability existing prior to entrance into the service, Capt. HARRY A. JEFFERSON, Clintonville.

Wyoming

To Fort Riley for duty, from Fort Riley, Lieut. LUTHER E. MITCHELL, Kaycee.

To Western Department for duty, Lieut. NEIL C. GEIS, Casper.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Smallpox.—During February and March, smallpox appeared in a number of cities and counties in the state. At Birmingham there were 100 cases early in February, the disease continuing to a greater or less extent throughout the month. The disease was reported from many communities throughout the country, and many cases occurred at Goodwater and other parts of Coosa County. At present it is abating, on account of the order from the health department requiring every one to be vaccinated as an emergency measure.

New Officers.—The Coosa County Medical Association, in session at Rockford, elected the following officers: Dr. Julius Jones, Rockford, president, and Dr. Cecil K. Maxwell, Kellyton, member of the registration board.

Full-Time Health Officers.—At Florence, Lauderdale County, $7,500 has been appropriated for the maintenance of a full-time health officer, a public health nurse and other necessary employees. This makes nine Alabama counties which have complete health departments.

ARKANSAS

State News.—More than 600 cases of smallpox were reported to the state board of health during February.——Action was taken at Fort Smith, March 7, toward the extension of the membership of the Union Hospital Association to make eligible all workers in Arkansas, Oklahoma and Texas. At the convention held at Fort Smith, a campaign was started to enlist 25,000 members in the association.——Rules were issued by the state board of health, March 6, with reference to the control and treatment of persons with venereal disease throughout the state.——March 10, the Arkansas Public Health Association began a campaign against tuberculosis at Marianna where the first field nurse of the association started a tuberculosis survey. The state board of health, the state department of education, the University Extension organization, and the Federation of Women's Clubs are assisting.——Dr. A. B. Brokaw of the International Health Board began a survey of health conditions in the southern district of Woodruff County, March 11.

CALIFORNIA

Personal.—Dr. L. Etta Farmer, Folsom, has gone to France to do general relief work among the refugees.——Dr. Robert A. Peers, Colfax, has been assigned to the Red Cross tuberculosis service in France.

License Revoked.—At Los Angeles, February 21, the licenses of the following physicians were revoked for various reasons: Drs. Thomas F. Glass, Moses Jacobson, William S. Carr, San Francisco, and George B. Wilson, San Bernardino. The last named physician was placed on probation for one year, as the result of his connection with the case of James H. N. Wilson, known as "Weeping Eye Wilson," who was convicted in the federal courts of attempting to defraud insurance companies by false claims of injury.

Miscellaneous.—At Los Angeles, March 7, an ordinance was passed providing that all food exposed for sale must be protected by glass. The ordinance will become effective in thirty days.——A medical school for the extensive training of medical officers for the United States Army was established in San Francisco, March 15. The school is directed by the associated faculties of the medical departments of the University of California and Stanford University. Classes of from ten to fifteen Army medical officers will be detailed to the school.

COLORADO

Personal.—Dr. Ralph S. Chamberlain has been named as county physician to succeed Dr. George P. Lingenfelter, who has resigned on account of his service in the United States recruiting office at Denver.——Dr. Harry S. Finney, Denver, has resigned as a member of the city health department.

Social Diseases.—Dr. Samuel J. Crumbine, Topeka, secretary of the Kansas State Board of Health was in Denver, March 2, as a representative of the National Council of Defense, to assist the state board of health and the Colorado Council of Defense in organizing a campaign against social diseases. Dr. Crumbine held a conference with Governor Gunter and the secretary of the state council of defense and other physicians and members. Dr. Crumbine is organizer of this work for the states of Colorado, Nebraska, Kansas, Texas, Oklahoma and New Mexico. The plans of organization have the following ends in view: a statute compelling the report of all social diseases, the creation of diagnostic laboratories, the establishment of free clinics under certain regulations, and the isolation and treatment of all women suffering from infections.

CONNECTICUT

Personal.—Dr. Seldon B. Overlock, Putnam, has been appointed a member of the state medical examining board. Dr. Frederick E. Wilcox, Willimantic, on the homeopathic board, and Dr. Leroy A. Smith, Higganum, on the eclectic board.——The Connecticut license of Dr. William L. Owen was revoked.——Dr. Arthur H. Baldwin, Norwalk, was seriously injured in an automobile accident, while making a hurried call.

DELAWARE

Officers Elected.—At Wilmington, the New Castle County Medical Society elected the following officers: Dr. John Ball, Elsmere, president; Dr. Harold L. Springer, Wilmington, vice president; Dr. Taleasiu H. Davies, Farmhurst, secretary-treasurer, and Drs. Harold L. Springer, Samuel C. Rumford and William H. Kraemer, all of Wilmington, members of the board of censors.

Personal.—Dr. Henry I. Stubbs, Wilmington, who had a serious operation performed on him at the Delaware Hospital, is convalescent.——Dr. William S. Hitch, Laurel, is critically ill with paralysis.——Dr. Vincent M. Myers, Wilmington, has resigned as secretary of the board of health to accept a position with a life insurance company in New York. The position left vacant by Dr. Myers has been filled by the appointment of Ex-Mayor Price, a civilian.——Dr. Allen A. Perkins, Hockessin, was reelected as city physician.

FLORIDA

Convalescent Hospital.—The government will establish a large convalescent hospital at Lake City, using the buildings of the Columbia College.

Free Distribution of Biologic Preparations.—The Florida State Board of Health has announced the inauguration of free distribution of antitoxin and vaccines. These products will be distributed from about twenty-five of the larger cities and towns of the state. Heretofore, it has been the plan for physicians to purchase such drugs for indigent persons and have them charged to the state. The products to be distributed are diphtheria, tetanus antitoxin, antimeningococcus serum and the pasteur treatment for rabies.

GEORGIA

Personal.—Dr. Charles D. Cleghorn has been elected superintendent of the Macon Hospital, to succeed Dr. O. E. Nichols, who will be attached to a Red Cross unit in France. Dr. Cleghorn is a roentgen-ray specialist who retired from practice several years ago.——Dr. T. F. Sellers has been appointed bacteriologist for the Georgia State Board of Health.

Neglect of the Ellis Law.—Answers to a questionnaire sent out by Dr. T. F. Abercrombie, secretary of the state board of health, disclose the fact that only eight counties have fully put into effect the Ellis health law which requires each county to establish health boards composed of three members, the county superintendent of schools, the director of the board of roads and revenues and one physician to be selected by the county grand jury. Boards have been organized in sixty-six counties, although grand juries in only eighteen have provided an active county health officer in the person of a physician. The chief neglect of the boards has been in the reporting of contagious and infectious diseases.

State News.—A new brick addition to the state sanatorium at Milledgeville was begun in February. This will accommodate 500 negro patients. Appropriation for the work was made by the legislature at its last session. On completion the building will have cost $89,250. The crowded conditions in the colored quarters made the new addition necessary.——Dr. Thomas F. Abercrombie, secretary of the state board of health, has asked for two medical inspectors for special work in meningitis and smallpox throughout the state.——An Atlanta firm has been awarded a contract by the War Industries Board to erect a tuberculosis hospital at Asheville, N. C., at a cost of $1,750,000.——Proprietary or patent medicines are to receive attention from the state board of health who will ask the legislature for restrictive legislation. The state board of health is conducting a campaign for the establishment of county health departments in counties where no such organizations exist. This is to be done under the Ellis law, which provides that such action may be taken on the recommendation of two successive grand juries. In counties where departments have been created, boards are urging health surveys in conjunction with the Rockefeller Foundation, one half of the expense of which is paid by the counties. Surveys are now being made in Troup and Tift counties. In view of the Ellis law regarding communicable disease, the state secretary has sent out thousands of cards to all county health boards on which reports of such diseases are to be made. The following is the complete list of diseases declared to be communicable and required to be reported to the state board of health: actinomycosis, acute infectious conjunctivitis, anchylostomiasis (hookworm), anthrax, cerebrospinal meningitis, chickenpox, cholera, dengue, diphtheria, dysentery (amebic), dysentery (bacillary), favus, German measles, glanders, gonorrhea, leprosy, malaria, measles, mumps, paratyphoid fever, plague, pneumonia (acute lobar), poliomyelitis, rabies, Rocky Mountain spotted or tick fever, scarlet fever, septic sore throat, smallpox, syphilis, tetanus, trachoma, trichinosis, tuberculosis (pulmonary), tuberculosis (other than pulmonary), typhoid fever, typhus fever, whooping cough, yellow fever.

IDAHO

Personal.—Dr. Roscoe N. Jackson, Sandpoint, has been appointed head of the state insane asylum at Blackfoot to succeed Dr. Walter F. Pike, resigned.——Dr. Leonard E. [illegible]nson, Wallace, was operated on at St. Luke's Hospital, [illegible]kane, for appendicitis.——Dr. D'Orr Poynter, Blackfoot, [illegible] been named as superintendent of the state sanitarium [illegible]bleminded at Nampa.

[illegible] News.—In the lumber camps of the panhandle district [illegible]te, smallpox and whooping cough have recently been prevalent.——At the camps of the Rose Lake Lumber Company the crews have been isolated on account of smallpox, which is said to be mild.——In carrying out the plans of the Surgeon-General of the Army, a campaign against venereal disease has been launched throughout the state.

ILLINOIS

General.—A special car costing $16,000 with stretcher capacity for six patients and seating room for thirty-two persons, has been provided and will be operated between the various psychopathic institutions of the state in transferring inmates.——For the use of the centennial records and exhibit soon to be held, Dr. Clifford E. Smith, president of the DeKalb County Medical Society, has asked for photographs of officers' homes, instruments, advertisements, prescriptions, etc., of pioneer physicians, and especially for copies of the medical journal published by Dr. Dunlap at DeKalb. Many interesting relics have already been collected.——Dr. Taylor, state supervisor of military zones, after a tour of inspection at Scott Field and other camps, has reported that East St. Louis must be cleaned up to make conditions safe for the camp at Belleville.——March 15, it was reported that there were twenty-eight cases of scarlet fever at Belleville and in the surrounding township.——The secretary of the state board of health, on account of the appearance of sporadic cases of infantile paralysis has sent out a general warning in regard to the disease.——The Peoria County Tuberculosis Sanatorium has been closed on account of the prevalence of insanitary conditions. A consultation was held between local officials and the director of the state department of health, March 13, regarding the sanatorium.——After an investigation of the epidemic of intestinal trouble at Peoria in which 3,000 persons were afflicted, the state analyst, who examined the water, said that it had been badly contaminated and might have been the cause of the trouble. The water at present, while not pure, is in much better condition.

Chicago

Society Meeting.—At the meeting of the Robert Koch Society for the Study of Tuberculosis at the City Club in Chicago, March 28, Dr. Everett Morris, Oak Forest, gave the results of induced pneumothorax in 202 cases of tuberculosis, and Dr. Burton H. Rogers read a paper with lantern demonstration of the subject of "The Barnyard as a Disseminator of Tuberculosis."

Personal.—Dr. Frederick A. Besley, major and director of Base Hospital No. 12 in France, has recently been detached from that unit and is now consulting surgeon in the field.——Mr. Edward R. Pritchard, for twenty years secretary in the city health department, was presented with two liberty bonds and tendered a banquet by physicians of the department and others, March 15, in recognition of his faithful service.

Miscellaneous News Items.—April 14 to 21 will be clean-up week in Chicago, and the plan is to make it a dustless operation.——The death rate in the city for the week ending March 9, according to the figures of the health department, was 14.8 per the [illegible]. For the same period of 1917 it was 18.1. [illegible] H. Farrell, survey officer and pathologist of the base hospital at Camp Travis, Texas, is now convalescing from pneumonia contracted in camp.——The sending of three typhoid patients from Whiting and Indiana Harbor, Ind., to Chicago led the health commissioner to protest to the Indiana authorities.

MARYLAND

Bureau of Child Hygiene.—The establishment of a bureau of child hygiene as a part of the Baltimore City Health Department, to prevent a high death rate among infants, is under construction. It has been recommended by Health Commissioner Blake, as a result of studies made by Dr. William T. Howard, Jr., assistant commissioner of health. The details are yet to be worked out.

More Patients at General Hospital No. 2.—An additional number of 101 patients arrived the latter part of the week at the United States Army General Hospital No. 2, Fort McHenry, from the U. S. Army General Hospital No. 1, Ellis Island, N. Y. A large number of the soldiers are from France. Twenty-five patients were transferred from the hospital at Fort McHenry to the Army hospital at New Haven, Conn.

Personal.—Dr. Kate B. B. Karpels, of the emergency dispensary of the Army Medical Department, has been given the relative rank of first lieutenant in the Army. Dr. Karpels is the first woman to receive such a rank.——Dr. William Rush Dunton, Jr., Townson, gave a talk on "War Work" at a meeting of the Children of the American Revolution in Baltimore, March 23.

NEW YORK

Third Course in Contagious Diseases.—The third course given this year in clinical and bedside instruction in contagious disease for registered physicians will begin at the Willard Parker Hospital, April 2. There are no fees, but those taking the course are expected to attend regularly.

Public Nurses for Rural Districts.—A bill has been introduced into the legislature to provide public nurses for rural districts. The measure authorizes one graduate nurse for every 15,000 population in each county, exclusive of the inhabitants of cities. The salaries of the nurses are to be $1,200 and the board of supervisors are required to supply the funds.

Protests Against Interference with Physical Training Law.—The American Physical Education Association, with headquarters in Springfield, Mass., has sent resolutions adopted by the association to Governor Whitman of New York earnestly requesting him to protect the health and physical education of the children of New York by keeping intact the present laws, which have been attacked in the legislature, or by promoting measures to make the laws more effective. The copy of the resolutions sent to the governor is signed by Dr. William Burdic, president; Dr. Dudley A. Sargent, Cambridge, vice president, and Edward H. Arnold, William A. Stecher and Randall D. Warden, members of the executive committee.

Classroom Ventilation and Respiratory Diseases.—In order to obtain more concrete evidence of the value of fresh air and to test the findings of the New York State Commission on Ventilation that some years ago made an investigation as to the comparative value of various systems of ventilation, the Bureau of Child Hygiene, in 1916, began an inquiry into the possible relationships between the prevalence of respiratory diseases among schoolchildren and classroom ventilation. The study was made in cooperation with the New York State Commission on Ventilation, which had full control of the selection of classrooms with reference to the type of ventilation to be included. This investigation was carried on among 5,533 pupils of seventy-six classrooms in twelve schools operated under three different types of ventilation. The investigation was conducted during a five-month period in the late fall, winter and early spring, and leads to the following conclusions: In the closed-window, mechanically ventilated type of classroom kept at a temperature of about 68 degrees F., the rate of absences from respiratory diseases was 32 per cent. higher than in the open-window, naturally ventilated type of classroom kept at the same temperature (about 68 F.) and about 40 per cent. higher than in the open-window, naturally ventilated type of classroom kept at a temperature of about 50 degrees. The relative humidity of classrooms, whether ventilated by natural or mechanical means, was not a causative factor in the occurrence of respiratory illness among schoolchildren.

New York City

Burke Foundation for Government.—Arrangements have about been completed whereby the convalescent home of the Burke Foundation will pass under the control of the government for the period of the war. The home which has accommodations for several hundred patients will be used as a convalescent home for soldiers.

Gifts and Bequests.—

To Jewish Charities, $1,000,000; Mount Sinai Hospital, New York, $37,500; the Montefiore Home, $37,000; the Hebrew Benevolent and Orphan Asylum, $27,000; Home for Aged and Infirm Hebrews, $17,000; Beth Israel Hospital, $12,500; German Hospital, $5,000; Hebrew Infant Asylum, $5,000; National Jewish Hospital at Denver, $3,500; the Hospital for Deformities and Joint Diseases, Skin and Cancer Hospital, Tuberculosis Preventorium for Children, the New York Eye and Ear Infirmary, each $2,500, by the will of Ludwig Dreyfus, some of these bequests to be paid immediately and others on the death of his wife.

Grip Epidemic.—New York is said to be suffering from a severe epidemic of the grip; but as this is not a reportable disease there are no figures by which the extent of the epidemic can be gaged. The health department has issued a set of precautions with a warning that grip is the most easily transmitted of all the highly contagious respiratory diseases. The figures of the health department indicate that pneumonia shows no signs of abating. During the week ending March 16, there were 426 cases as against 247 for the corresponding week of 1917. Sing Sing Prison reports that there are thirty patients suffering from grip in the prison hospital, and about seventy in the dormitory and cell block.

OHIO

Postgraduate Course.—The Cleveland Academy of Medicine announces to its members who have paid their dues for 1918 a free postgraduate clinical and didactic course in pediatrics, surgical diagnosis, casualty surgery, physical diagnosis, genito-urinary diseases, syphilis, gynecology and gross pathology.

PENNSYLVANIA

State to Care for Wounded.—March 21, Governor Brumbaugh appointed a committee to form plans for the physical restoration, education and employment of convalescent and disabled soldiers. The committee will cooperate with the Surgeon-General's Office in Washington, D. C., and various schools in the state will provide quarters and training. More than 30,000 industrial establishments have offered to care for disabled soldiers, 1,829 alone being open to men who have lost their power of speech through shell shock.

State News.—A service flag containing thirty-two stars will be dedicated at the April meeting of the Fayette County Medical Society.——Drs. G. Franklin Bell, Williamsport, Edward Lyon and John A. Campbell were appointed a special committee by the Lycoming County Medical Society to make a report on the features of the Pennsylvania workmen's compensation law, in which the physicians are interested.——The only man among the 400 employees of the Middletown car shops who evaded vaccination during a recent epidemic came down with smallpox. Four cases of smallpox occurred among the colored population of Harrisburg leading to the vaccination of 500 persons, March 11.——At a meeting at Bloomsburg, March 14, the Montour and Columbia county medical societies agreed to meet together hereafter.

Personal.—Dr. Samuel McC. Hamill, Philadelphia, has been named chairman of the newly formed child welfare committee of the Council of National Defense and will lead a campaign to save at least 100,000 babies. Through the women's committee, known as the state council section of the Council of National Defense, the subdivisions of the problem of child welfare, such as infant mortality and the development and care of children of preschool age, have been taken up and the importance of cooperation with state, municipal and county health departments has been urged. Physicians and nurses trained in child welfare and public health work, as well as volunteer workers, will be supplied by the committee to counties of the state.——Dr. Isaac Shirk Simons, Elizabethtown, Lancaster County, was shot and severely injured while attending a patient, March 9.——Dr. Maria White, India, having relatives in New Castle, has been at Camp Lee, Va., studying parasitic diseases, at the instance of the authorities.——Dr. Theodore C. Harter, Bloomsburg, will be a candidate for state senator.——Dr. Benjamin F. Royer, Harrisburg, acting commissioner of health, will deliver the memorial address on the late commissioner, Dr. Samuel G. Dixon, at the Academy of Natural Sciences, Philadelphia, April 9.——Dr. Albert M. Sittler was elected president and Dr. Harvey Balliet, health officer of the Bowmanstown Board of Health.——Dr. Simon S. Koser and his wife, Dr. Cynthia E. Williams-Koser, Williamsport, have leased their private hospital to the managers of the Williamsport Private Hospital, recently burned, and will travel for two years in California and Alaska.——Dr. Albert F. Bronson, Girardville, will be a candidate for the legislature.——Dr. J. Spencer Callen, Shenandoah, will be a candidate for the legislature.——Dr. Mary B. Newell has been appointed resident physician at the tuberculosis hospital, Pittsburgh. She was formerly in hospital service in Chicago.

Philadelphia

War on the Mosquito.—Plans to eliminate the mosquito from southwest Philadelphia as health precaution for the thousands of workers at the Hog Island shipyard and other industrial plants were formulated in the office of Dr. Wilmer Krusen, director of public health and charities, March 20. The work will be performed jointly by the city and the state, with the assistance of the industrial establishments themselves. Last year the work was confined to the lowlands between Broad Street and the Delaware River. The department of public works has a fund of $10,000 for the work.

The Alumni Society Elects Officers.—At the annual meeting of the Philadelphia Alumni Society, medical department, University of Pennsylvania, held February 16, the following officers were elected: president, Dr. S. Lewis Ziegler; honorary president, Provost Dr. Edgar Fahs Smith; first vice president, Dr. Henry J. Off; second vice president, Dr. John J. Robrecht; third vice president, Dr. William S. Wray; corresponding secretary, Dr. Stephen E. Tracy; recording secretary, Dr. W. Oakley Hermance; treasurer, Dr. Herbert B. Carpenter; executive committee, Drs. B. Franklin Stahl, Harvey E. Schock, Paul J. Sartain and McCluney Radcliffe, and Clarence P. Franklin.

SOUTH CAROLINA

Board of Health Appointments.—At Charleston, Dr. J. Merceir Green has been reappointed health officer, and Dr. Charles P. Aimar and Dr. Henry W. J. de Saussure were reappointed members of the board of health.

General.—At Florence, action has been taken to open a tuberculosis clinic for whites and negroes, and to employ a visiting nurse. After attending a conference of health officers at Atlanta where health conditions in the cantonment zones was discussed. Dr. H. C. Cody, Spartanburg, reported improvement in conditions throughout the territory, and said the problem for Spartanburg was to eliminate mosquitoes and malaria, and the fly and typhoid fever. He urged better collection of garbage for the city.——The last session of the state legislature appropriated $5,000 for fighting tuberculosis among cattle and cholera among hogs. Three veterinarians will be employed and an active campaign begun.——Dr. Luther A. Riser, executive secretary of the South Carolina Antituberculosis Association reports that $10,000 was realized from the sale of Red Cross seals.

TENNESSEE

State Medical Association Meeting.—The eighty-fifth annual session of the Tennessee State Medical Association will be held at Memphis, April 9, 10 and 11. The association is among the oldest state associations in the United States. Jan. 1, 1918, it had 1,600 members, out of a total of 2,741 physicians in the counties represented in the association, while there were 287 physicians in counties not represented.

General News.—Five cases of smallpox developed among the nurses at the Ellinger Hospital at Chattanooga in the latter part of February and the hospital was quarantined by Dr. Carlisle P. Knight, United States Public Health officer, who was in charge in this zone. All persons exposed were vaccinated.——Work on the new Memphis and Shelby County Tuberculosis Hospital at Memphis was held up early in March on account of matters of procedure. The rules for the conduct of the hospital have now been adopted. Dr. John M. Maury, Memphis, has been named on the board of trustees.——The examination of 3,300 men on construction work at the Bend, near Nashville, showed little disease or disability. All unprotected men were vaccinated.——At Knoxville, an ordinance has been proposed requiring the examination for contagious or infectious disease four times a year of all restaurant, hotel and boarding house employees.——Dr. Carlisle P. Knight of the United States Public Health Service will visit health officers in all parts of the state in the interest of the campaign against venereal diseases.

TEXAS

Personal.—Dr. Robert J. Gauldin, Dallas, has resigned as vice chairman of the state board of health.——Dr. Royal S. Loving, secretary of the Dallas County Medical Society has resigned to enter the military service; Dr. William W. Fowler was elected to fill out the unexpired term.——Dr. Charles F. Card, Justin, has been made first assistant health officer at Dallas in charge of the work of visiting physicians and quarantine officers, and Dr. Vernando P. Armstrong, Dallas, has been appointed second assistant in charge of the emergency hospital, the city ambulance and the visiting nurses.

Miscellaneous.—The division of sanitation of the health department at Dallas has completed the spring survey of streams and other breeding places of mosquitoes and adopted measures for their elimination. Dr. Alva W. Carnes, Hutchins, health officer, deplored the difficulty of getting sufficient help at the emergency hospital. The food and sanitation divisions have been commended for the satisfactory condition of health matters in their jurisdiction. During February there were seventy-six cases of smallpox and 425 cases of measles. An amendment to the food ordinance has been proposed governing outside displays of food.——Representative Carlock has introduced a bill into the legislature advocated by the Texas Social Hygiene Association making venereal diseases reportable under the file number of the physician.——At Fort Worth a clinic is to be established for the treatment of venereal diseases which will be in charge of a specialist of the United States Public Health Service. Two probation officers, a social worker and nurses to be furnished by the Red Cross complete the personnel.——At Dallas a free tuberculosis clinic will be established. Dr. Raleigh W. Baird has been chosen chairman of the clinic committee.——At a special meeting of the Bexar County Medical Society at San Antonio, March 12, the program consisted of a symposium on pneumonia. Papers were read by Dr. Rufus J. Cole and Capt. Alphonse R. Dochez, M. R. C., of the Rockefeller Institute, New York, and Dr. William G. MacCallum, professor of pathology, Johns Hopkins Hospital, Baltimore.——For the purpose of improving sanitary conditions in the smelter district at El Paso, on the solicitation of Dr. Will Rogers, county health officer, the county commissioners appointed a special board of health for the district, on which they named Dr. Will Rogers, Dr. Louis G. Witherspoon and Mr. Will Hord.

UTAH

Personal.—Dr. William R. Brown has been appointed city physician of Ogden.—Dr. LeRoy C. Potter, assistant physician at the state mental hospital, Provo, has resigned and will resume general practice.——Dr. Herbert C. Deane has resigned as registrar of vital statistics a[illegible] [illegible] P. S. Hagefan has been appointed health [illegible] to fill the vacancy caused by the removal of Dr. Herbert C. Deane to Idaho.——Dr. E. M. Conroy has been made chairman of the Weber County Council of Defense at Ogden.

Miscellaneous.—It is announced that a free dispensary for the treatment of the social diseases will be opened at Salt Lake City in connection with the emergency hospital.——The state health commissioner, Dr. T. B. Beatty, assisted by two federal government representatives, will begin a vigorous campaign for a better reporting of births, which is desirable for war reasons. It is hoped to place the state within the registration area.——At Logan efforts are being made to establish better reporting and more effective quarantine of infectious diseases. The chairman of the local board of health has called on citizens and physicians for better cooperation. An ordinance on the subject has been prepared.

VIRGINIA

Reorganizing the City Health Department.—Under the new plan of organization of the health department provided for under the ordinance of February 20, at Norfolk, the health department will consist of three members, with a health director, who need not be a member of the community or the state. Dr. George M. Converse, of the United States Public Health Service, has been appointed director. The plan creates a new health district, which is under the joint control of the city, the United States Public Health Service and the American Red Cross, and comprises territory in which are located a number of the Army cantonments, hospitals and camps.

Personal.—Dr. William S. Keister, Richmond, has gone to San Antonio, Texas, where he will be in charge as one of the health officers of the war camps located near the city. He has been connected with the Virginia state health service. His father, Dr. B. C. Keister, has discontinued his sanatorium and will convert the building into apartments.—The salary of the state health commissioner, Dr. Ennion C. Williams, Richmond, has been increased by the state legislature from $3,500 to $5,000.——Dr. R. L. McMurran, Portsmouth, has been appointed by the governor quarantine medical inspector for the division of Elizabeth City for the term of two years.——Dr. James R. Speight has been appointed assistant to Dr. Powhatan S. Schenck, health commissioner of Norfolk, to fill the position made vacant by the resignation of Dr. Claiborne Willcox, New Rochelle.——Dr. Philip W. Boyd, Winchester, has been appointed member of the state board of health.——Dr. James W. Reed, Ocean View, was elected health officer of Norfolk County.

WASHINGTON

Miscellaneous.—Dr. John B. Anderson, city health officer of Spokane, has been required by the state board of health to quarantine all patients with social diseases, beginning April 1, and physicians will be required to report all such cases.

The patients will be isolated in the Rivercrest Contagious Hospital.——At the meeting of the Pierce County Medical Society at Tacoma, March 10, the Commercial Club presented the society with a service flag bearing thirty-two stars representing the number of members who have joined the colors.

Personal.—Dr. Robert J. Skaife, Colfax, has been appointed county health officer to succeed Dr. Frank A. Bryant, who has gone into the Army medical service.——Dr. Hilbrand J. Hards has resigned as city health officer at Tacoma.——Dr. J. Glen Harbison has been made chairman of the committee on health and sanitation of the Spokane Chamber of Commerce, to succeed Dr. Nathan M. Baker. Other physicians on the committee recently appointed are Drs. Frank Holmes, C. O. Linder, Alexander R. Lundgren, Spokane, Sutherland J. Wolff and Edison Worthington.

WEST VIRGINIA

Personal.—Dr. Grover C. Robinson, Charleston, has been appointed superintendent of the state hospital at Spencer in the place of Dr. Charles A. Barlow, resigned.——Dr. William T. Morris, Wheeling, has been appointed deputy inspector of the Scottish Rite in West Virginia.——Dr. Ralph W. E. Cole, formerly of Akron, Ohio, has been appointed state epidemiologist, to fill the vacancy caused by the resignation of Dr. Harold B. Wood.——Dr. Edward H. Thompson, Bluefield, has been made a member of the state health council to succeed Dr. Luther H. Clark, Kyle, resigned.——Dr. Harold B. Wood, Wheeling, has been appointed epidemiologist in the New York State Department of Health.

WISCONSIN

Personal.—Dr. Francis R. Salisbury of Sparta is suffering from a nervous breakdown, following severe infection of a wound.——Dr. John F. Brown, Sparta, superintendent of the state school, has been appointed acting mayor since the death of Dr. Fred P. Stiles.

Miscellaneous.—Twenty-seven cases of infantile paralysis have occurred in Milwaukee since January 1. There have been three deaths.——Three cases of scarlet fever in St. Elizabeth's Hospital at Appleton caused the exclusion of all visitors and the postponement of surgical operations not of an emergency nature.——The new county sanatorium for tuberculosis at Pewaukee Lake in Waukesha County has been completed at a cost of $32,000.——At Beloit, March 14, the office of Dr. Malcolm P. Andrews was robbed of cocain, cash and surgical instruments, it is believed, by drug users. ——About 150 pounds of digitalis, raised last year in the drug gardens of the University of Wisconsin at Madison, will be placed at the disposal of the medical service of the Army.

CANADA

Personal.—Lieut.-Col. D. King Smith has returned to Toronto from Halifax and is now commanding officer of the North Toronto Military Hospital.——Capt. James Douglas Shields, Mount Albert, Ont., has returned to Canada from overseas and has been appointed assistant medical adviser on the pension board at Ottawa.——Major L. Bruce Robertson, C. A. M. C., who has been overseas since the beginning of the war, has been recalled by the University of Toronto. Major Robertson was attached to No. 2 Canadian Casualty Clearing Station.

Hospital News.—According to the tenth annual report of the Harbor View Hospital at Sydney Mines, N. S., 501 patients were treated in 1917, with twenty-three deaths. The financial report showed a credit balance of $5,013.48.——The late James I. Carter, Sarnia, Ont., left the Hospital for Sick Children, Toronto, $30,000.——In 1917, the Western Hospital, Montreal, admitted 1,388 patients. The cost of maintenance per day was $3.01. It was the hardest financial year the hospital has had, as the deficit stood at $40,324.79.——The Protestant Hospital for the Insane at Verdun is reported overcrowded, having 771 patients. It has been extremely difficult to find nurses. The financial year closed with a deficit of $38,471.——Jeffrey Hale's Hospital, Quebec City, added during the past year the James Douglas Tuberculosis wards for advanced cases. Thirty beds in the institution are now devoted to military purposes. During 1917, 901 patients received treatment.——The Laval Hospital, which is being built in Quebec City for the treatment of cases of tuberculosis, will be opened about May 1. It will be used as a clinic for teaching purposes in connection with Laval University. Accommodation will be provided for 135 patients and treatment will be given free of charge. The government of Quebec contributed $25,000 for the erection of the institution, and the city of Quebec a like amount, the remainder being provided by private contribution.——The board of control of Winnipeg has granted $58,600 to cover the deficits in the last year's annual statement of the King George and King Edward Hospitals of that city.——Dr. Maurice McD. Seymour, commissioner of public health, Saskatchewan, opened a new hospital at Eston, Sask., in January.——During the past year, hospitals have been established at Lloydminster, Edam, Eston, and Shaunavon, Sask., and the necessary by-laws have been passed for similar institutions at Davidson, Rosetown, Kerrobert and Lampman. Estevan, Outlook and Lanigan defeated similar by-laws.——A military sanatorium is planned at Kananaskis, near Banff, Alta. It is to cost $400,000, one half to be paid by the Dominion government, and the remainder by the province of Alberta. It will accommodate 300 patients, and when no longer required for military purposes, will become the property of Alberta for the treatment of civilian patients.

GENERAL

Next Examination of National Board.—The National Board of Medical Examiners will hold its next examination at Fort Oglethorpe, Ga., beginning April 8. A little later another examination will be held at Fort Riley, Kan.

Tuberculosis.—According to the estimate of the National Association for the Study and Prevention of Tuberculosis, within the next two years 50,000 more beds will be needed in the United States to care for the indicated increase in tuberculosis on account of war conditions. There are said to be 43,000 beds available at present. The estimate is based on evidence of the incidence of the disease as disclosed by the selective draft. It was formerly estimated that for every death from tuberculosis there were five cases, but it is now believed the true number of cases is two or three times as great. Instead of about 1,000,000 active cases in the country there are probably between 2,000,000 and 3,000,000. The military examinations show that an average of about 2 per cent. of young men of draft age are tuberculous, and this average is confirmed by the experiment at Framingham, Mass.

FOREIGN

Malta Fever.—It was announced from Paris, February 26, that Prof. M. A. Vincent of the Academy of Medicine had developed a vaccine against malta fever.

American Child Welfare Congress.—The Second American Child Welfare Congress, which was to have been held at Montevideo in March, has been postponed to December, 1918. Prof. L. Morquio of Montevideo is chief of the executive board.

Pneumonic Plague.—It was reported, February 24, that pneumonic plague had broken out in Shansi Province, China, that the epidemic had assumed serious proportions and that all northern China was threatened. Five years ago, 30,000 or 40,000 deaths occurred from this disease, which was combated and studied by an international committee of experts.

The Interallies Surgical Association.—Our Danish and Netherlands exchanges comment with disapproval on the change of the International Surgical Association to be an Interallies Association. Pinkhof in the Netherlands weekly remarks that it reminds him of Heine's poem in which he related that in a fever he dreamed that he was pounding his enemy with mighty blows but that the pain of the blows was felt by the pounder, not the poundee.

Relief Units for Palestine.—February 28, it was announced that four medical units for civilian relief work in Palestine following the wake of the British army would be organized at the request of the British government. The funds were to come from the American, Armenian and Syrian relief fund and be administered by the American Red Cross. The American Jewish Relief Committee has appropriated $100,000 for a medical unit for Palestine, and Mrs. Peter J. Schweitzer of Brooklyn has given $25,000 for the treatment of trachoma in that region.

Italian Medical Students in the Army Sent Back to Study.—The *Riforma Medica* states that a recent decree has been issued which orders all mobilized and nonmobilized medical students inscribed in the "third and fourth *corso di medicina*" to return to their respective universities and continue their studies, the courses having been especially speeded up for the purpose. The number of students affected by the decree is 2,300, and they are to be housed in special quarters arranged by the *Comando Supremo.* Special liberty and special conditions are to be given them so they can make the most of the opportunities for study thus provided.

CORRECTION

"Iodids in Roentgenography."—In the article by D. F. Cameron on "Iodids in Roentgenography," which appeared in The Journal, March 16, page 754, an error occurred in the following sentence: "It is worthy of note that the opacity of the silver iodid preparations that have been commonly used is probably due to the iodid rather than to the silver content." The latter part of the sentence should read: ". . . is probably due more to the iodid than to the silver content."

PARIS LETTER

Paris, Feb. 21, 1918.

War Wounds of the Kidney

At a recent meeting of the Société de chirurgie de Paris, Dr. Chevassu, professor agrégé à la Faculté de médecine de Paris and chirurgien des hôpitaux, reported 56 cases of unquestionable wounds of the kidney, of which 46 were recent and 10 old wounds. The wounds of the kidney were accompanied by wounds of the liver in 11 cases; of the lung in 9; of the stomach in 2; of the colon in 3; of the small intestine in 3, and of the spinal cord or the lumbar plexus in 3 cases. A number of cases were accompanied by diverse wounds of the skull or of the extremities. In 21 cases the kidney alone seemed to have been injured.

Leaving out of consideration the possible gravity of associated wounds of other viscera, wounds of the kidney are serious for two reasons: hemorrhage or infection. The gravity from hemorrhage is not very considerable. Among the 46 recent cases, Chevassu saw only 6 cases of severe or grave hemorrhage (3 internal, 2 hematuria); 5 of these terminated fatally; the sixth was nephrectomized and a cure resulted. Among the other cases the hematuria was inconsequential, lasting only a few days or sometimes only one day, or even only for the first micturition, and not being alarming in degree. In 5 cases seen by Chevassu a perirenal hematoma was produced, manifesting itself as a lumbar or lumbar-iliac tumor which was easily detected. In two cases he found it advisable to operate because of high fever; one of these patients died; the other was cured. The other 3 patients were treated expectantly, and all recovered. In the remaining 35 cases there were no special symptoms of renal origin, other than the hematuria, some retraction of the body wall on the affected side, and frequently, at first, phenomena of shock, common in so many cases of abdominal wounds.

PLAN OF TREATMENT

In these 35 cases, in which the symptoms did not demand *a priori* medical treatment directed toward the kidney specially, the following course was pursued: primary operation, 11 cases; secondary operation, 2 cases; not operated on, 22 cases. The primary operations comprised 1 nephrectomy (1 death); 7 lumbar drainages (1 death); 3 interventions on other organs than the kidney (colon, 2 cases, 1 death; peritoneum, 1 case, 1 death). The two secondary operations were directed to the associated as well as the kidney lesions: purulent pleurisy, 1 case (1 death), incision of an intraperitoneal abscess (1 case with cure). There remain 22 cases in which neither abdominal, lumbar nor thoracic operation was done although several of the men were operated on for wounds of the brain or of the extremities. Of these 22 cases which were treated expectantly (absolute rest, proper diet and hexamethylenamin), 3 terminated fatally and 19 were evacuated. Of 28 cases in which pieces of projectile were embedded, 10 terminated fatally, 36 per cent. mortality, and 18 seton cases had 4 deaths, 22 per cent. mortality. The greater mortality among the projectile cases is due to the persistence of the hematuria or secondary hemorrhage and infection.

HEMORRHAGE AND INFECTION

The immediate treatment of wounds of the kidney demands that cognizance be taken of two serious conditions—hemorrhage and infection. The first is relatively slight, at least among the conditions habitually observed in an automobile ambulance. The seve internal hemorrhages, which sometimes accompany wound of the kidney, seem to be associated with the other bleeding ounds at least as often as if not oftener than with the injur of the kidney itself. In either case, operation to secure hemos is is indicated. In the case of the kidney, this nearly alwa means a nephrectomy, because in these cases there is always need for haste; but a kidney should never be removed without knowing something about its fellow. Hematuria, alone, is not an indication for operation, unless it is menacing because of its persistence and abundance. As for the operations other than nephrectomy, suture of the lacerated kidney is a very difficult procedure; tamponage, for an organ as movable as the kidney, does not appear ever to have arrested a hemorrhage which would not have been arrested spontaneously; but one can conceive that in some cases, fortunately, the lesion is limited and a partial nephrectomy may be indicated.

Apart from the operative indication of hemorrhage, is it advisable to intervene systematically in all cases of kidney wounds for the purpose of insuring disinfection? Chevassu does not believe that this course is indicated in the seton wounds. Experience has shown that most of the abdominal and thoracic seton wounds heal spontaneously. In cases in which the projectile is still in the tissues, should one apply systematically to wounds of the kidney the usual formula: excision of the projectile track, and removal of the missile? Chevassu does not believe in this now, for many reasons: (1) because it has been shown that many of these foreign bodies lodged in the kidney region are tolerated well, especially when they are small; (2) because in many of these cases there is danger of inflicting much damage during the removal of the foreign body; (3) because the treatment of the renal wound, if it is infected, seems to be hazardous, unless a partial nephrectomy is done, and that often leads to a total nephrectomy. Only the large shell fragments, which can be removed without too much damage, may be regarded as an indication for immediate operation. As for the others, it is better not to operate at once; if they give rise to symptoms, a secondary operation can be done.

OLD WOUNDS OF KIDNEY

So far as old wounds of the kidney are concerned, Chevassu has seen only 10 cases in the hospital service of the interior. Of these 10 cases (all of from five to eighteen months' standing) none had been subjected to an immediate operation; 3 had been operated secondarily: removal of a shell fragment from the kidney on the eighteenth day; opening of a perinephritic abscess on the fifteenth day; removal of a lumbar projectile *à froid.* One of these cases presented a urinary fistula which disappeared spontaneously in about two months. Of these 10 patients, 1 sought medical attention because of pyuria, 1 for nephritis, 2 for pain; the other 6 had been sent by the *Commissions de réforme* for study of their renal function, although they did not present any appreciable symptoms. Two of these patients still carried a shell fragment in the perirenal zone; 7 had normal micturition and voided a clear urine; 2 voided a muddy urine; one of these urines did not contain any pathologic product. A comparative study made of both kidneys of 7 patients by means of ureteral catheterization showed a marked inferiority of the wounded kidney in 2, including 1 with the healed fistula; in 3, both kidneys were approximately equal, including a man who had had an intrarenal shell fragment removed on the eighth day; in 2, paradoxical as it may seem, there was a slight increase in the secretion on the wounded side. On the whole, therefore, a considerable number of these old kidney wound cases do not present any appreciable stigmata, determinable by exploratory procedures of precision. Hence, these experiences justify surgeons at the front in being as conservative as possible in cases of wounds of the kidney.

Treatment of Intra-Ocular Foreign Bodies

At a recent session of the Académie de médecine, Dr. de Lapersonne, professor of clinical ophthalmology on the Faculté de médecine de Paris, presented a very important paper discussing the indications for treatment of intra-ocular foreign bodies incident to war wounds. His conclusions are as follows: 1. Among the war wounds, the small intra-ocular shell fragments present grave dangers, and often entail blindness in one or even both eyes. 2. In spite of the difficulties that have hitherto stood in the way of the adoption of measures for the protection of the eyes against shell fragments, it is important to insist on the use of visors, goggles or masks. 3. Foreign bodies should be extracted at once. It is indispensable that autonomous ophthalmologic services should be installed in the hospital centers, one or two for each army, and that the rapid transfer of the wounded to these services be assured. They should be independent of the surgical automobiles and should have a special radiologic installation, with electromagnets and a complete supply of instruments. 4. Radioscopy being known to be insufficient for the diagnosis of the presence of these small foreign bodies it is necessary that the radiologic installation permits exact locating by making a number of negatives if necessary.

Sale of Condensed Milk

The council of public hygiene and of health of the department of the Seine has adopted the following resolutions with regard to the sale of condensed milk: 1. Condensed milk, either sweetened or unsweetened, should contain all the natural ingredients of milk in their normal proportions. 2. Condensed skimmed milk, sweetened or unsweetened, whose food value and marketable value is inferior to those of condensed whole milk, must carry on the label, in plain letters, the word "Skimmed" or the words "Do not give to infants or to the sick." 3. Condensed milk cannot be made from partially skimmed milk. 4. The box should be stamped with the date (month and year) of filling or packing. 5. It should also be stamped to show the quantity of milk (per volume) of normal composition that can be "reconstructed" from the contents of the box. If sweetening is required, the label should show the amount of sugar (saccharose) which the milk should contain when "reconstructed." 6. The label should further state that it is essential to boil the "reconstructed" milk, especially if it is intended for infants. 7. The addition of saccharin to condensed milk should be interdicted. 8. The foregoing rules and regulations also apply to dried or evaporated milk.

LONDON LETTER

LONDON, March 5, 1918.

Another Hospital Ship Sunk by the Germans

The hospital ship *Glenart Castle*, with about 200 persons on board including the medical staff and nurses, was torpedoed at 4 a. m., February 26, in the Bristol Channel, and sank in seven minutes; 153, including all the female nurses (who numbered eight) are missing, and it is feared drowned. Immediately after the explosion the lights went out and the wireless system was rendered ineffective. The ship went down stern first, which made the launching of boats extremely difficult even if there had been sufficient time. Fortunately there were no patients on board. The captain stood on the bridge to the last, and was heard to tell the quartermaster to get away to the boats. He apparently went down with the vessel. Seven out of the nine boats were successfully launched, but some of them were not fully occupied. This brings the number of British hospital ships sunk within the past twelve months up to seven. All were torpedoed without warning during the night.

Retirement of Sir Alfred Keogh

Sir Alfred Keogh has retired from the position of Director-General of Medical Services and resumed work as rector of the Imperial College of Science and Technology. He has been one of the few unalloyed successes of the war. The results achieved by the Army Medical Service are largely due to his prevision. They can be estimated by comparison with the much smaller South African War, in which the whole British force rarely exceeded 200,000, and there were 57,000 cases of typhoid fever. On this basis we should have expected half a million in the present war, but there have been little more than 3,000. In South Africa 721 officers and 7,091 men were killed or died of wounds, a total of 7,812; and 339 officers and 12,911 men, a total of 13,250, died of disease. In a recent fortnight, the published lists of casualties in all theaters of the present campaign show 646 officers and 7,453 men killed or died of wounds, a total of 8,099. In the same period, eight officers and 303 men "died," that is, of disease, a total of 311. The number of reported killed and wounded in this fortnight exceeded that of the whole of the South African campaign, while the number who died of disease did not reach one fortieth of the number who succumbed from this cause. In other figures, while in the South African War of every hundred deaths sixty-three were due to disease, in the present campaign the loss from this cause in one typical fortnight is less than four in every hundred deaths. The health of the troops at home is better than that of the civil population; that of those in France, better than the average health of the army in peace time. Elsewhere, even where there is a special risk of disease, health statistics give no cause for undue anxiety.

On the occasion of his reelection as president of the Association Technical Institutions Sir Alfred Keogh said: "The proudest thing I feel in connection with this campaign is that science has been vindicated in its relation to administration. If we have accomplished anything it has been that we have succeeded in preventing those diseases which in all previous campaigns have wiped out armies, literally, and that has been due to the fact that for some years past we have been engaged in teaching the army what is the relation of science to military work."

On the occasion of his retirement, Sir Alfred Keogh was entertained at dinner and presented by consulting physicians and surgeons with a gold cup. In proposing his health, Sir Berkeley Moynihan said that Sir Alfred had established at home, in France, in Greece, Palestine, Egypt, Mesopotamia, in many outposts of the empire, 2,500 hospitals, which were at least the rivals of the very best civil hospitals that were to be found in this country before the war. Our armies in the field had been sheltered from the ravages of disease with unexampled security. There had been fewer cases of typhoid fever than there were deaths from typhoid fever in South Africa, though our army was now ten times as large as it was then, and though the conditions in respect to climate and environment were much worse. Sir Alfred Keogh was the parent of constructive sanitary reform in the British Army. In Egypt, bilharziosis, which had existed from the time of the Pharaohs, and claimed one third of the male population of the country as its victims, had been studied by a commission sent out by Sir Alfred Keogh, and as a result it might be predicted that the disease was in process of rapid extinction. Most valuable scientific work had been done in malaria, dysentery, trench fever, cerebrospinal meningitis, tetanus, and a large number of medical and surgical conditions.

The Treatment of Malaria

The large number of cases of malaria in soldiers returned from overseas and concentrated in special hospitals in England has led the War Office to institute a scheme of comparison of the results obtained by different methods of treatment. They have been summarized by Sir Ronald Ross, the adviser of the War Office in these matters, in a paper read at the Society of Tropical Medicine. The treatments adopted are classified into (*a*) "antirelapse quinin prophylaxis," designed for preventing relapses as much as possible without attempting absolute and immediate cure; (*b*) "short sterilizing," which attempts absolute cure with treatments ordinarily continued only for a few days; (*c*) "long sterilizing," aiming at producing absolute cure by longer courses than in short sterilizing, and (*d*) mixed treatments, and treatments with drugs other than quinin. The criterion of success is the disappearance of relapses during the observation periods practicable. In nearly all the cases the malaria (mostly benign tertian) was already of considerable duration. The treatment comprised different preparations of quinin, administered by mouth and by subcutaneous, intramuscular and intravenous injections in different doses and for different periods. The result from all the quinin treatments taken together is represented by 27 per cent. of ascertained relapsing cases in a total of about 2,500 patients. A control was afforded by 192 men, who were watched without any quinin treatment at all. Of these, eighty-nine relapsed within twenty-seven days, and seventy-six were presently judged not to be sufficiently well to allow of quinin treatment being withheld any longer, so that 86 per cent. of the untreated patients remained ill, and 46.5 per cent. actually suffered from relapses during the period. The conclusion is that short, intensive treatment by large doses of quinin (for example, up to 180 grains of quinin sulphate or hydrochlorid in three days) with rest, stimulants, and good after-treatment is well borne and effects a substantial proportion of cures. The same can be said for doses in Class C, which in some instances totaled over 1,000 grains in four weeks, large intramuscular doses being given during the first days of that period. But, however, the doses were given in Classes B and C, the liability to relapse in patients receiving the treatment was not any less than in cases treated much less heroically under the method of Class A, by giving comparatively small doses amounting to about 60 grains a week. Doses of this order gave the best results both in respect of the prevention of relapses and as regards the well-being of the patient. This dosage can be distributed in various ways without producing any marked difference. The amount should not, however, be less than a daily dose of about 10 grains, as this showed a marked superiority over smaller quantities. No conspicuous advantage was found in any one of the three methods of administration of quinin, intramuscular, intravenous or oral. Chemical examinations point to a tendency for the excretion of quinin, in whatever doses given, to reach a concentration of from 7 to 11 grains per quart of urine, and show that the drug is not eliminated more rapidly when given by the mouth than when given by other channels.

THE CHICAGO SESSION

List of Chicago Hotels Recommended by the Local Committee on Arrangements

The local Committee on Arrangements, on recommendation of its subcommittee on hotels, urges that those who plan to attend the Chicago session, June 10 to 14, should make their selection and write directly to the hotel, stating the accommodations desired and indicating the rate they are prepared to pay. The management of the hotel should be advised of the day on which guests expect to arrive in Chicago, and the length of time they plan to remain. If, in any instance, a satisfactory arrangement with some one of the hotels is r made, write to the chairman, subcommittee on hotels, Dr. C. Whalen, 25 East Washington Street, Chicago.

The accompanying table lists a number of Chicago hot indicating the accommodations which are offered and nami the rates per day. All rates are for accommodation on t European plan except when, as indicated, the American pl is offered.

Deaths

ose **Lewis Hirsh, M.D.**, Baltimore; University of Maryland, iool of Medicine, Baltimore, 1895; aged 45; a Fellow of American Medical Association; professor of clinical liatrics, pathology and bacteriology in the University of ryland; visiting pathologist to the University Hospital, l consulting pathologist to the Hospital for Women of ltimore, Md.; died suddenly, March 17, from heart disease.

eorge Amos White, M.D., Sacramento, Calif.; Long Island llege Hospital, Brooklyn, 1869; Jefferson Medical College, iladelphia, 1870; aged 69; a Fellow of the American Med- l Association; a member of the Pacific Association of ilway Surgeons, and division surgeon of the Southern cific Railway Company; founder of the White Hospital, cramento; died at that institution, March 3.

Lieut. William Thomas Gleason, M.D., M. R. C., U. S. my, Ely, Nev.; Rush Medical College, Chicago, 1902; aged , formerly a Fellow of the American Medical Association; a mem- r of the Nevada State Medical ssociation; died on the platform the Denver and Rio Grande Sta- on, Salt Lake City, while on a rlough to visit his wife and child, arch 7, from heart disease.

John Patrick Grimes, M.D., Men- d, Ill.; University of Illinois, Col- ge of Medicine, 1899; aged 42; member of the Illinois State Med- al Society; for several years a ember of the staff of St. Joseph's lospital; physician and surgeon to e Southern Illinois Penitentiary, lenard; died at St. Andrew's Hos- ital, Murphysboro, Ill., March 14, om cerebral meningitis.

Albert Mehrer Moore, M.D., hiladelphia; Medico-Chirurgical ollege of Philadelphia, 1905; aged l; a Fellow of the American Med- cal Association; a member of the ohn Heissler Anatomical and Sur- ical Society; assistant demonstra- or of anatomy in the Medico- hirurgical College Hospital; died t his home, March 6, from cerebro- pinal meningitis.

John Calvin Schofield, M.D., Bal- imore; Baltimore University, chool of Medicine, 1891; aged 53; ormerly professor of nervous dis- ases and diseases of the throat nd chest, and assistant professor f pathology in the University of laryland; for many years local urgeon of the Baltimore and Ohio ailroad; died at his home, larch 7.

Died in the Service
AT CAMP DIX
LIEUT. HAROLD FRANKLIN MICKLEY, M.D., M. R. C., U. S. ARMY, 1890-1918

Lieut. Harold Franklin Mickley, M.D., M. R. C., U. S. Army, eneca Falls, N. Y.; New York Homeopathic Medical Col- ge, New York City, 1912; aged 27; a Fellow of the Amer- an Medical Association; a member of the staff of the base ospital at Camp Dix, Wrightstown, N. J.; died at the base ospital, March 16, from lobar pneumonia.

George Halley, M.D., Kansas City, Mo.; Victoria Univer- ty, Medical Department, Coburg, Ont., 1869; aged 78; one f the organizers of the Kansas City Medical College, and ntil 1892 was professor of principles and practice of surgery; etiring to take a similar position with the University Med- al College; died at his home, March 11.

Albert Jeffrey Cox, M.D., Superior, Wis.; Rush Medical ollege, Chicago, 1886; aged 56; a Fellow of the American ledical Association; formerly a member of the Minnesota tate Medical Association; surgeon for the Chicago and orthwestern Railroad; formerly a practitioner of southern linnesota; died at his home, March 13.

Samuel C. Stewart, M.D., Clearfield, Pa.; Jefferson Med- al College, Philadelphia, 1881; aged 61; formerly a Fellow f the American Medical Association; a member of the ledical Society of the State of Pennsylvania; formerly chief of the staff of the Clearfield Hospital; died at his home, March 11, from cerebral hemorrhage.

Olof Sohlberg, M.D., St. Paul; Minneapolis Hospital Medical College, Minneapolis, 1884; aged 58; a Fellow of the American Medical Association; for many years a member of the board of directors and visiting staff of the Bethesda Hospital, St. Paul; died on a train en route to St. Paul, March 6, from cerebral hemorrhage.

J. Marshall Elder, M.D., Franklin, Ill.; Physio-Medical College of Indiana, Indianapolis, 1896; aged 46; a Fellow of the American Medical Association; a member of the American Association of Physio-Medical Physicians and Surgeons; died at the Passavant Hospital, Jacksonville, Ill., March 1, following an operation.

Henry Rohlfing, M.D., St. Louis, Mo.; Missouri Medical College, St. Louis, 1883; aged 56; formerly a Fellow of the American Medical Association; a member of the Missouri State Medical Association; formerly professor of bacteriology at the University of Missouri; died at his home, February 19, from nephritis.

William Jabez Nickerson, M.D., New Bedford, Mass.; Bowdoin Medical School, Portland, Me., 1871; aged 73; formerly a Fellow of the American Medical Association; a member of the Massachusetts Medical Society; a veteran of the Civil War; died at his home, March 6, from cerebral hemorrhage.

John Walter Costolo, M.D., Sidney, Ohio; Medical College of Ohio, Cincinnati, 1883; aged 65; formerly a Fellow of the American Medical Association; a member of the Ohio State Medical Association; formerly superintendent of the District Tuberculosis Hospital at Lima; died at his home, March 7.

James P. Hanner, M.D., Franklin, Tenn.; University of Pennsylvania, School of Medicine, Philadelphia, 1857; aged 82; formerly a Fellow of the American Medical Association; captain and surgeon of the Confederate Army from 1861 to 1865; died at his home, March 6, from pneumonia.

John Franklin Southmayd, M.D., Brooklyn; Columbia University College of Physicians and Surgeons, New York City, 1892; aged 49; formerly a member of the Medical Society of the State of New York; chief surgeon to the Brooklyn Union Gas Company; died at his home, March 12.

John Wesley Duncan, M.D., Atlanta, Ga.; Atlanta (Ga.) Medical College, 1868; aged 75; formerly a Fellow of the American Medical Association; a member of the Medical Association of Georgia; one of the oldest practitioners of Atlanta; died at his home, March 11.

Susan Maria Smith McKinney Steward, M.D., Wilberforce, Ohio; New York Medical College and Hospital for Women, Homeopathic, New York City, 1870; aged 72; a colored practitioner; resident physician of the Wilberforce University; died at her home, March 7.

Frank Roop Smith, M.D., Wilmington, Del.; University of Pennsylvania, School of Medicine, 1893; aged 62; also as analytical chemist of the College of Pharmacy of Philadelphia; died suddenly at his office while attending a patient, March 6, from heart disease.

Lieut. Claude A. Harmon, M.D., M. R. C., U. S. Army, Upton, Wyo.; Starling Medical College, Columbus, 1904; aged 38; for many years mayor of Upton; died at the State Hospital, Sheridan, Wyo., March 11, from injuries received in a railway accident.

Charles Augustus O'Dea, M.D., Erie, Pa.; Niagara University Medical Department, Buffalo, 1895; aged 43; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; died at his home, March 9.

Ransford De Los Canedy, M.D., North Adams, Mass.; Columbia University, College of Physicians and Surgeons, New York City, 1896; aged 45; for many years a member of the city board of health; died at his home, March 11, from pneumonia.

Horatio Franklin Copeland, M.D., Whitman, Mass.; Harvard University Medical School, 1865; aged 75; a Fellow of the American Medical Association; a veteran of the Civil War; died at his home, January 8, from cerebral hemorrhage.

Charles Masters Cain, M.D., Indianapolis, Ind.; Indiana University School of Medicine, Indianapolis, 1909; aged 34; a member of the Indiana State Medical Association; died at the Methodist Hospital, March 8, from acute enteritis.

Lydia A. Bickford, M.D., New York City; New York Medical College and Hospital for Women, Homeopathic, 1894; aged 69; one of the oldest medical practitioners of the city; died at the New York Hospital for Women, March 9.

Elmo W. Hopson, M.D., Lockesburg, Ark.; Hospital College of Medicine, Medical Department, Louisville, 1906; aged 42; formerly a member of the Arkansas Medical Society; died at Horatio, Ark., January 13, from tuberculosis.

Marion Howard Cazier, M.D., Detroit; Rush Medical College, Chicago, 1880; aged 67; formerly a Fellow of the American Medical Association; a member of the Illinois State Medical Society; died at his home, about March 4.

Elton J. Palmer, M.D., Philmont, N. Y.; Jefferson Medical College, Philadelphia, 1878; aged 68; formerly a member of the Medical Society of the State of New York; died at his home, March 9, from cerebral hemorrhage.

John Robinson Gildersleeve, M.D., Richmond, Va.; Medical College of Virginia, Richmond, 1864; aged 75; a Fellow of the American Medical Association; a veteran of the Civil War; died, March 5, from heart disease.

John S. Tryon, M.D., Rehrersburg, Pa.; University of Pennsylvania, School of Medicine, Philadelphia, 1857; aged 84; for many years a practitioner of Berks County; died at his home, March 6, from senile debility.

Edward Stanislaus Dougherty, M.D., Ashley, Pa.; Jefferson Medical College, Philadelphia, 1900; aged 42; a Fellow of the American Medical Association; died at his home, March 6, from cerebral hemorrhage.

William Lee Howard, M.D., Westboro, Mass.; University of Vermont, College of Medicine, Burlington, 1890; aged 57; formerly of Baltimore; and author of many books on sex hygiene; died in Boston, March 11.

Brig.-Gen. Charles Tripler Alexander, U. S. Army, retired, Washington, D. C., aged 84; a veteran of the Civil War; formerly in charge of the Medical Supply Depot, New York City; died at his home, March 1.

Ralph E. Moeser, M.D., Montrose, Ill.; Hahnemann Medical College, Kansas City Mo., 1910; aged 33; a member of the Illinois State Medical Society; died from injuries in an automobile accident, March 8.

Charles Seymour Bradley, M.D., Boston; New York University, New York City, 1873; a member of the Medical Society of the State of New York; died at his home, January 10, from heart disease.

Ellen M. Osburn, St. Louis, Mo. (license, Missouri, 1894); aged 50; founder and former head of the Ellen Osburn Hospital, St. Louis; died at the Mayfield Memorial Hospital, March 8, from cancer.

John H. Burrow, M.D., Milan, Tenn.; University of Nashville, Tenn., 1862; aged 84; for more than fifty years a practitioner of Gibson County; died at the home of his daughter in Milan, March 1.

Elijah Tracy Bishop, M.D., Smithsburg, Md.; University of Maryland, 1855; aged 85; a member of the Medical and Chirurgical Faculty of Maryland; died at his home, March 11, from paralysis.

Allen B. Becker, M.D., Springwater, N. Y.; Baltimore University School of Medicine, 1890; aged 58; health officer of Livingston County, N. Y.; died at his home, January 14, from pneumonia.

Linn L. Kennedy, M.D., Washington, D. C.; Louisville (Ky.) Medical College, 1887; aged 46; for several years a practitioner of Louisville and Tuscaloosa, Ala.; died at his home, March 5.

John W. Smith, M.D., Vevay, Ind.; Chicago Homeopathic Medical College, 1885; aged 61; a member of the Indiana State Medical Association; died at his home, March 2, fro arteriosclerosis.

Thomas D. Johnson, M.D., Clarksville, Tenn.; Washingt University School of Medicine, Baltimore, 1869; aged 76; veteran of the Civil War; died at his home, March 6, fro senile debility.

Walter Barrows Hayward, M.D., Taunton, Mass.; Bost University School of Medicine, Homeopathic, 1897; aged 4 died at the Massachusetts Homeopathic Hospital, Bosto March 10.

George Ivan Pohek, M.D., Pittsburg, Kan.; University Munich, Germany, 1882; aged 63; formerly a Fellow of tl American Medical Association; died at his home, March 1

Silas Stevenson, M.D., Ellwood City, Pa.; Western Reser University, School of Medicine, 1868; aged 73; a veteran the Civil War; died at his home, March 8, from senile debilit

Dudley Thomas Boyd, M.D., Ector, Texas; Vanderbi University, Nashville, Tenn., 1892; aged 47; a Fellow of tl American Medical Association; died at his home, February

John W. Roberts, M.D., Irving, Texas; Fort Worth Un versity Medical Department, 1910; aged 33; a Fellow of tl American Medical Association; died at his home, March 9.

John A. Hagar, M.D., Gloversville, N. Y.; Albany (N. Y. Medical College, 1890; aged 53; health officer of Fulto County, N. Y.; died at his home, March 6, from paralysis.

Elmer A. Doty, M.D., Oxford, Iowa; State University c Iowa, Iowa City, 1885; aged 67; a Fellow of the America Medical Association; died suddenly at his farm, March 7.

Alexander C. Fraser, M.D., Pasadena, Calif.; McGill University, Montreal, 1877; aged 60; for many years a practitioner of Manitowoc, Wis.; died at his home, March 7.

Arthur Rubel Keith, M.D., Rockford, Ill.; University o Pennsylvania, Philadelphia, 1907; aged 35; died at Utica N. Y., February 21, from pulmonary tuberculosis.

Carl Flucks, St. Wendells, Ind. (license, Indiana, 1898) aged 70; a member of the Indiana State Medical Association died at Perry, Ark., February 5, from pneumonia.

Redington Stanhope, M.D., Lincoln, Neb.; Western Reserve University, School of Medicine, Cleveland, 1880; aged 81; died at his home, January 19, from pneumonia.

James W. Speer, M.D., Alton, Ky.; Miami Medical College, Cincinnati, 1867; aged 81; a veteran of the Civil War; died at a hospital in Frankfort, Ky., March 5.

Frederick Roesch, M.D., Chicago; University of Heidelberg, Germany, 1852; aged 88; died at the home of his daughter, March 21, from senile debility.

Harry D. Riordan, M.D., Kansas City, Mo.; Kansas Medical College, Topeka, 1908; aged 41; died in the Lafayette Hotel, Kansas City, about March 2.

James Randolph Humes, M.D., Hollidaysburg, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1874; aged 70; died at his home, March 9.

Marshall Robin Morden, M.D., Adrian, Mich.; University of Michigan, Ann Arbor, 1871; aged 73; died at his home, March 13, from senile debility.

Emory Valentine Buck, M.D., New York City; New York University Medical College, New York City, 1872; aged 75; died at his home, March 16.

John T. Moore, Mooresville, N. C. (license, North Carolina, 1898); died near Mooresville, March 12, from injuries received in an automobile accident.

Clarence Linden Howes, M.D., Hanover, Mass; Long Island College Hospital, Brooklyn, 1878; aged 69; died at his home, March 7, from pneumonia.

Benjamin P. Wilson, M.D., Lake Butler, Fla.; Charity Hospital Medical College, New Orleans, 1876; aged 66; died in Sneads, Fla., March 10.

Marriages

Lieut. Carroll Seman Thomson, M. R. C., U. S. Army, Clinton, Mich., to Miss Ruth Ardele Hovarter of Chicago, March 21.

Lieut. Carl Herman Bartling, M. R. C., U. S. Army, Chicago, to Miss Katherine Stewart of York, N. Y., March 23.

Alfred Pfitsch, M.D., Baltimore, to Miss Eva Margaret Williams of Federalsburg, Md., March 6.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

NOSTRUMS IN RETROSPECT

A Review of Worthless or Unscientific Proprietary Mixtures Previously Criticized

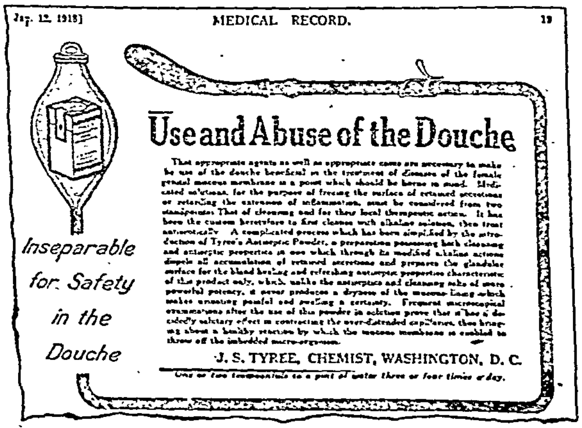
[FOREWORD.—The article that follows is the eighth[1] of a series written for the purpose of reviewing the findings of the Council on Pharmacy and Chemistry on certain unscientific or worthless proprietary mixtures advertised to physicians. Although the preparations taken up in this series have been dealt with in previous reports, the fact that they are still widely advertised and prescribed indicates the need of further publicity. The writer of the series is thoroughly conversant with the work of the Council on Pharmacy and Chemistry and can speak authoritatively on questions dealing with the actions of drugs in the treatment of disease.]

[ARTICLE VIII.]

TYREE'S ANTISEPTIC AND ASEPTINOL

By S. Q. Lapius, M.D.

It may seem paradoxical to say that recent progress in the nedical sciences has made therapeutic chaos possible, but it s true nevertheless. Revolutions are sometimes slow and rderly, sometimes sudden and attended with confusion. The evolutionary changes in the medical sciences have been so umerous and so rapid that the general practitioner has been unable to keep pace with them, and in the resulting confusion the nostrum maker has seen his opportunity for exploiting his useless, dangerous or unscientific preparations. The greater the confusion the greater his opportunity, and it is no exaggeration to say that he has been the most potent factor in maintaining the chaos of therapeutics.



Inseparable for Safety in the Douche

Jan. 12, 1918] MEDICAL RECORD. 19

Use and Abuse of the Douche

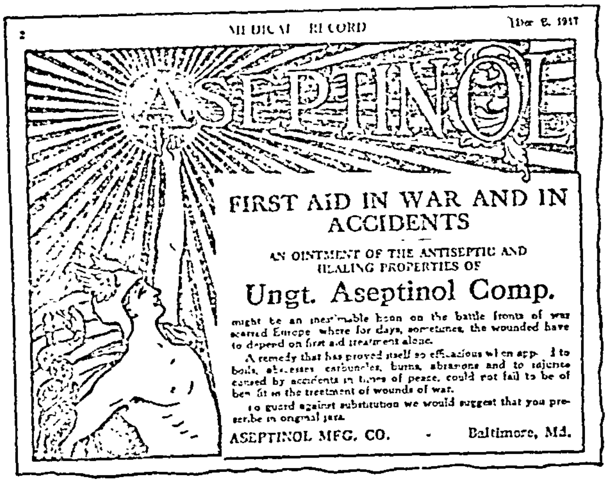
That appropriate agents as well as appropriate care are necessary to make the use of the douche beneficial in the treatment of diseases of the female genital mucous membrane is a point which should be borne in mind. Medicated solutions for the purpose of freeing the surface of retained secretions or retarding the extension of inflammation, must be considered from two standpoints: That of cleansing and for their local therapeutic action. It has been the custom heretofore to first cleanse with alkaline solution, then treat antiseptically. A complicated process which has been simplified by the introduction of Tyree's Antiseptic Powder, a preparation possessing both cleansing and antiseptic properties in one which through its modified alkaline actions dispels all accumulation of retained secretions and prepares the glandular surface for the bland healing and refreshing antiseptic properties characteristic of this product only, which unlike the antiseptics and cleansing salts of more powerful potency, it never produces a dryness of the mucous lining which makes urinating painful and swelling a certainty. Frequent microscopical examinations after the use of this powder in solution prove that it has a decidedly salutary effect in contracting the over-distended capillaries, thus bringing about a healthy reaction by which the mucous membrane is enabled to throw off the imbedded micro-organism.

J. S. TYREE, CHEMIST, WASHINGTON, D. C.

One or two teaspoonfuls to a pint of water three or four times a day.

cal half-page Tyree advertisement appearing in medical journals.

ie majority of our readers would probably say that the ing scientific medical literature insures the permanence stablished beliefs, but every one who has delved into the ature has found instances of truths that had been estab- d and forgotten—buried under the ever-increasing anche of contributions to that literature. Rapid advances are still being made in the medical sciences and unless constant vigilance is exercised therapeutics will return to the chaotic condition from which it has so recently emerged. It was in recognition of these facts—the danger of this return to chaos, and the difficulty, in fact impossibility, of any individual keeping pace with all of the medical sciences —that the American Medical Association secured the cooperation of men in various branches of medicine in the Council on Pharmacy and Chemistry, in order that it may place the results of therapeutic progress before readers of THE JOURNAL in an impartial manner.



2
MEDICAL RECORD
Dec. 8, 1917
ASEPTINOL

FIRST AID IN WAR AND IN ACCIDENTS

AN OINTMENT OF THE ANTISEPTIC AND HEALING PROPERTIES OF

Ungt. Aseptinol Comp.

might be an inestimable boon on the battle fronts of war scarred Europe where for days, sometimes, the wounded have to depend on first aid treatment alone.

A remedy that has proved itself so efficacious when applied to boils, abscesses, carbuncles, burns, abrasions and to injuries caused by accidents in times of peace, could not fail to be of benefit in the treatment of wounds of war.

To guard against substitution we would suggest that you prescribe in original jars.

ASEPTINOL MFG. CO. - Baltimore, Md.

Typical Aseptinol advertisement.

Are you profiting by this work, or are you still depending on your unaided efforts to distinguish the false teachings of the nostrum venders from that of scientific medicine? Are you prescribing "Antikamnia" and "Ammonol" or a simple member of the group such as acetanilid or phenacetin? Are you depending on "Tyree's Antiseptic," so called, or are you using an antiseptic about which there is no mystery, for which no false claims are made, and one which is really effective? In short, are you using drugs of unquestioned value, such as are described in "Useful Drugs" or are you taking your therapeutic instructions from nostrum makers' circulars?

Perhaps you have been led to believe that the Council on Pharmacy and Chemistry is composed of "theorists" and that the nostrums represent the work of "practical men." Every one should strive to be practical, of course, and it is worth while to inquire whether scientific experimenters, who so largely mold medical literature, should be termed theorists, or practical men. A practical man practices that which is useful in the treatment of the sick, and he must determine who is capable of furnishing him with a better materia medica. A perusal of medical literature will convince any unbiased mind that medical science progresses only by means of experiment, hence experimenters must be considered the really practical men while those who cling to outworn theories are really the "theorists."

When Lister introduced antiseptic methods into surgery he inaugurated a veritable revolution, which afforded the nostrum makers opportunities for reaping rich harvests through the exploitation—under extraordinary claims—of cheap mixtures of little, or no, value. There is no lack of antiseptics of extraordinary activity in the test tube that are practically harmless to man, and it would seem natural to suppose that such antiseptics could be used to control the development of bacteria in such diseases as typhoid fever, but, unfortunately, such hopes have not been fulfilled. Ehrlich experimented with many phenol derivatives that showed decided antiseptic activity in the test tube, in the hope that he might find some that could be used to combat such common diseases as diphtheria and typhoid fever, but while many of these are of low toxicity for man, he was unable to find even one that could be used effectively in the treatment of any of these diseases. His discovery of arsphenamin

---

The previous articles of the series are "Bell-ans," THE JOURNAL, 24, 1917; "Anasarcin and Anedemin," Dec. 8, 1917; "Peptogan," Dec. 29, 1917; "Cactina Pillets," Jan. 19, 1918; "Ammonol Phenalgin," Feb. 2, 1918; "Fellows' Syrup and Other Preparations he Hypophosphites," Feb. 16, 1918; "Shotgun Nostrums," March 918.

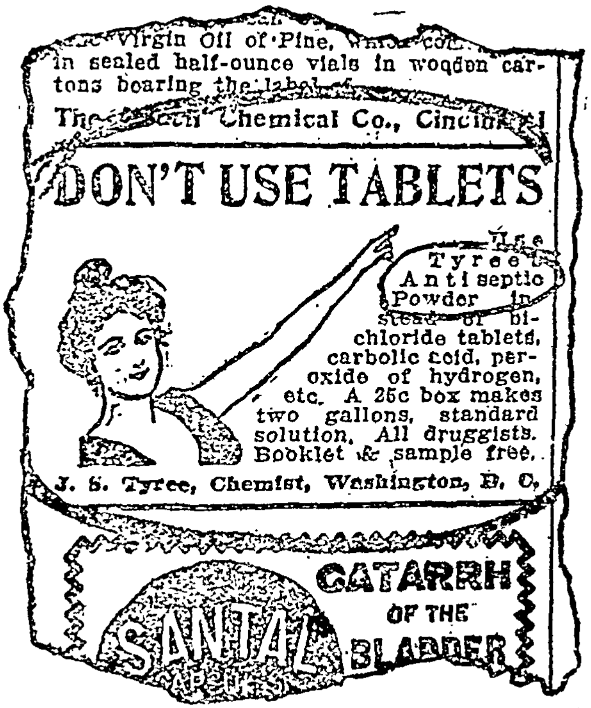
("salvarsan") resulted from quite another type of investigation.

Many practitioners lose sight of the essential difference between antiseptics and disinfectants and employ antiseptics in cases where only a disinfectant action would be of value. An antiseptic does not destroy bacteria, it merely inhibits their growth, and when it is diluted too much it loses its effects and the bacteria may begin to multiply as though no antiseptic had been used. This is especially true after the use of weak antiseptics in the mouth. These are soon diluted or removed by the saliva, and the bacteria continue to multiply with only a momentary interruption at best, hence to advise the use of an oral antiseptic as an effective means of treating diphtheria is little short of criminal.

"Tyree's Antiseptic Powder" was submitted to the Council nearly twelve years ago. The label on the package stated:

> "This preparation is a scientific combination of borate of sodium, alumen, carbolic acid, glycerin and the crystallized principles of thyme, eucalyptus, gaultheria and mentha in the form of a powder."

A leaflet issued several years ago by the Aseptinol Manufacturing Company states that "Pulv. Aseptinol Comp." combines in an elegant form boric acid, the salts of aluminum, crystallized phenol, and the active crystalline principles of thymus, mentha and gaultheria.



Virgin Oil of Pine,
in sealed half-ounce vials in wooden cartons bearing the label of
The Chemical Co., Cinci

DON'T USE TABLETS

Use Tyree's Antiseptic Powder instead of bichloride tablets, carbolic acid, peroxide of hydrogen, etc. A 25c box makes two gallons, standard solution. All druggists. Booklet & sample free.

J. S. Tyree, Chemist, Washington, D. C.

SANTAL CATARRH OF THE BLADDER

One of the older newspaper advertisements of Tyree Antiseptic Powder.

A comparison of these formulas would justify the designation of the two preparations as twins, but even a twin can have a wart where the other lacks it. The formula of Pulv. Aseptinol Comp. given in the leaflet also includes hydrastis canadensis, but we believe that a wart would be quite as much of an addition to the anatomy of man as the hydrastis is to this already preposterous formula. Similar as the formulas of these two nostrums were said to be, the general methods of exploiting them were even more similar. A partial list of the diseases for which each has been recommended by its exploiters shows the similarity of methods pursued:

Tyree's was Said to be Useful in the Treatment of:	*Pulv.* Aseptinol Comp. was Said to be Useful in the Treatment of:
Leucorrhea	Leucorrhea
Gonorrhea	*Gonorrhea*
Vaginitis	Vaginal inflammation
Pruritus	*Pruritus*
Ulcerated conditions of the mucous membrane	Ulceration of vagina or cervix
Scrofulous ulcers	Chronic ulcers
Syphilitic ulcers	Prophylactic against specific disease
Disinfecting offensive cavities	*Cleansing pus cavities*
Deodorant	Deodorant
Profuse and offensive perspiration	Checks abnormal secretion

We stated that the formula furnished by Tyree was th given above, but the Council was never able to learn wh Tyree actually employed the formula except for advertisi purposes, and analysis of the powder showed that Tyre Antiseptic Powder was essentially a mixture of boric ac and sulphate of zinc, with insignificant amounts of odoro principles.

A remarkable fact brought out in the course of the co sideration of the preparation by the Council was that Tyr admitted that he had changed the formula without havi published the new one. The Council then showed that specimen of the "antiseptic" that had been kept in a ret drug store for several years was essentially similar to th sold at the later date. Thus it would seem that Mr. Tyr had been making his powder by one formula and publishi an entirely different one for years before the Council pu lished the facts in the case.

If Tyree found it necessary to change the formula of h powder—if indeed, he ever used the published formula—w did the *Aseptinol Manufacturing Company adopt it, or o* so closely resembling it?

It is obvious that both of these twin nostrums are utter unfit for treating the various conditions for which they a or have been recommended, and in view of the misrepresе tation in one case, it is difficult to understand why it shoul be taken as the model for the other. Do physicians belie that a simple mixture of boric acid and zinc sulphate, or *mixture such as that given in the formula of* "Aseptino powder, is *in any way superior to a prescription such as an* physician could write?

There is a far more important question to consider tha the relative merits of such nostrums and a prescription o the physician's own devising, and that is whether the medica profession is going to help to perpetuate the chaotic condition that the use of such nostrums foster or to assist in therapeuti progress by maintaining its independence of such false teachers, and seeking to aid in the establishment of a rational us of drugs and remedial measures.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RESISTANCE OF THE ORGANISMS OF GONORRHEA AND SYPHILIS OUTSIDE THE BODY

To the Editor:—Please publish the opinion of authorities on the life of gonorrheal and syphilitic organisms outside the human body.

H. T. M.

Answer.—The gonococcus is sensitive to drying, and in ordinary conditions can survive exposure to the air for only a short time, although in dried pus it may live as long as six or seven weeks. Linen soiled with discharges may transmit the disease after a fairly considerable time; but if the linen is placed in boiling water, the organism is killed very rapidly.

Zinsser and Hopkins have shown that when kept moist, the *Spirochaeta pallida* can live in a diffuse light and at room temperature under conditions of mixed culture, such as would occur in ordinary contamination of materials from the condition, as long as eleven and one-half hours. Drying kills the organisms rapidly, but during the drying period they may survive as long as one hour.

COMPATIBILITY OF PHENOLPHTHALEIN

To the Editor:—Are calomel and phenolphthalein compatible in the same powder or capsule?

George D. Carnes, M.D., South Haven, Mich.

Answer.—A reply to this query was published in The Journal, Feb. 8, 1913, p. 466. In brief, it is better not to combine several laxatives, but for those who believe in doing this it is easy to combine with phenolphthalein most drugs that can properly be prescribed in powders or pills. There appears to be no reason why calomel should not be combined with this drug so far as chemical compatibility is concerned; and since both are tasteless, they may be prescribed together either in the form of powder or enclosed dry in capsule, cachet or wafer. However, the discriminating physician will estimate the amount of each ingredient according to the susceptibility of the patient, and if phenolphthalein is depended on as the active laxative, the mixture should be made for only a few doses in order that the amount of phenolphthalein may be changed without unduly large doses of the other ingredients being given.

ACTIVITY AFTER INJURY TO HEART

To the Editor:—Please give your opinion in the next issue of THE JOURNAL as to whether a man, 31 years of age and in previous good health, who had received the injury described below, could walk or run a distance of approximately 254 feet after the infliction of the injury described? A bullet entered the body 2 inches above and 1 inch to the right of the right nipple, thence passed through the right lung, the heart and left lung, and passed out of the chest and lodged under the skin in the left axilla. Blood was found in both chest cavities, and the pericardium contained loose blood. H. W. B.

ANSWER.—It is impossible to answer definitely this particular hypothetic question. There are, however, authentic reports of cases in which persons have been able to walk or run considerable distances after heart injuries. Paré records the case of a soldier who received a blow from a halberd which punctured the left ventricle and who walked to the surgeon's tent to have his wound dressed, and then to his own tent 250 yards away. Roberts (*Richmond and Louisville Medical Journal*, 1871, **12**, 2607) describes a man who ran 60 yards and lived one hour after being shot through both lungs and the right auricle.

HEAT CRAMP

To the Editor:—In one of the 1908 issues of THE JOURNAL, Dr. D. S. Edsall had an article dealing with heat stroke and heat cramps. Can you give me any information pertaining either to his works or to other works along this line, either in pamphlet or in book form? I am especially interested in the question of heat cramp in industrial workers.

A. P. HANCUFF, M.D., Youngstown, Ohio.

ANSWER.—The article by Edsall appeared in THE JOURNAL, Dec. 5, 1908, p. 1969. Queries and Minor Notes on this subject appeared in THE JOURNAL, June 1, 1912, p. 1706; Nov. 9, 1912, p. 1734, and July 8, 1916, p. 143. Following is a list of references:

Diathermy in Treatment of Gonorrhea.—According to an abstract in the *Correspondenz-Blatt*, Müller has recently reported excellent results from application of diathermy in treatment of gonorrhea in the male in 175 cases. He ascribes the benefit more to the hyperemia and the loosening up of the tissues than to the direct destruction of the gonococci by the heat. Hence he follows the diathermy with injection of warm disinfectants, as the mucosa is practically sensitized by the preceding diathermy. He found that this combination was effectual even in old chronic cases and with inflammatory processes in the prostate, seminal vesicles and epididymis; the urine cleared up and the tendency to sexual neurasthenia subsided. In his communication in the *Dermatologische Wochenschrift*, he insisted that no injurious by-effects of any kind were observed.

Arkansas Eclectic November Examination

Dr. C. E. Laws, secretary of the Arkansas Eclectic Medical Board, reports the written examination held at Little Rock, Nov. 13-14, 1917. The examination covered twelve subjects and included 120 questions. An average of 75 per cent. was required to pass. Seven candidates were examined, all of whom passed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Georgia Coll. of Eclectic Med. and Surg.	(1915)* 84.4; (1916)	84.7
Kansas City College of Med. and Surg.	(1917) 77.1, 78, 80.4, 81.1,	86.3

*Graduation not verified.

Kentucky December Examination

Dr. A. T. McCormack, secretary of the State Board of Health of Kentucky, reports the written examination held at Louisville, Dec. 4-6, 1917. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 12 candidates examined, 9 passed and 3 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
University of Louisville	(1916) 78, 78; (1917)	79, 85, *
Lincoln Memorial University	(1917)	80
Meharry Medical College	(1916) 73; (1917)	71, 72
FAILED		
University of Louisville	(1912)	66
Lincoln Memorial University	(1911) 63; (1917)	62

* No grade given.

Lousiana December Examination

Dr. E. W. Mahler, secretary of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, Dec. 6-8, 1917. The examination covered 11 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 18 candidates examined, 9 passed and 9 failed. Four candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Chicago College of Medicine and Surgery	(1916)	79.9
Tulane University of Louisiana	(1917) 76.2, 76.6, 76.7, 77, 87.1,	88.7
University of Pennsylvania	(1903)	87.6

Book Notices

The Principles and Practice of Dermatology. Designed for Students and Practitioners. By William Allen Pusey, A.M., M.D., Professor of Dermatology in the University of Illinois, Emeritus. Third Edition. Cloth. Price, $7. Pp. 1243, with 466 illustrations. New York: D. Appleton & Co., 1917.

The author has completely revised this book, and has elaborated on many subjects, particularly pellagra and syphilis. One of the best sections of the work is the preliminary chapter on the anatomy of the skin, illustrated by twenty-nine excellent pictures, and presenting material which should be known to every physician who attempts to treat disorders of the skin. The section on treatment is probably more conservative and rational than that appearing in any other textbook on diseases of the skin. The prescriptions given are simple, and few contain the numerous ingredients that so frequently mark dermatologic prescriptions.

Particularly interesting is the view that the author holds of vaccine therapy:

> The method of treatment by the use of vaccines has so appealed to the medical imagination, and the use of stock vaccines has been made so easy by the manufacturers of bacteriologic products, that vaccine therapy has had an enormous vogue. . . . As dermatologists have had experience with the method in the last five years it has lost ground in their confidence, and this failure to hold its place as an efficient remedy among dermatologists is perhaps the best evidence of the inefficiency of the method. In so far as the use of vaccines has tended to encourage the indifference to other details of treatment, and a slipshot and indiscriminate therapy, they have been actually harmful.

The discussions on the use of the roentgen ray, radium and light therapy are equally conservative, the advantages and disadvantages being pointed out in definite, positive statements. In his discussion of the etiology of pellagra, the author does not seem to accept wholly either the deficiency, the maize or the parasitic theory, although he states that the theory that pellagra is caused by a parasite and transferred by some biting insect has much to commend it. This was probably written some time ago, as the more recent work of the United States Public Health Service indicates that the deficiency theory should receive more prominence. The section on syphilis has been greatly extended and covers 156 pages. It includes an article on the Wassermann reaction by Dr. A. W. Stillians, and is a veritable treatise on this most important condition.

There are 466 halftone illustrations in the book, but none in colors, which detracts somewhat from the value of the book for those not especially familiar with the appearance of dermatologic lesions.

A Treatise on Regional Surgery. By Various Authors. Edited by John Fairbairn Binnie, A.M., C.M., F.A.C.S. Three Volumes. Cloth. Price, $7 each. Philadelphia: P. Blakiston's Son & Co., 1917.

This is a three volume work on regional and special surgery. That part of general surgery which relates to the principles of pathology and therapy has been omitted. The aim of the work is to present short treatises on the injuries and diseases of the different regions of the body. It is a work of many authors, each dealing with a different subject or subjects. The editor admits that there is overlapping and repetition, but says that "when it occurs it is interesting and instructive to note the differences in the views expressed by the different authors." The editor thinks this is an advantage; we would regard it as a disadvantage. In a review of a work covering so many subjects and by so many authors it is impossible to take up in detail the various opinions expressed. One general feature that is quite noticeable and commendable is that the authors enter at once on the subject in hand, without wasting time and space with the usual commonplace introductory remarks. What the authors have to say they say in a few words and stop. Sometimes they quit before the subject is really covered. As is usual in composite works, some articles stand out prominently by reason of their excellence, while others, by comparison, are mediocre. The editor might have used his privilege occ sionally and substituted proper pharmacopeial for proprieta or trade names. The volumes are of convenient size, abo 600 pages each, and are well illustrated.

Social Medicine, Medical Economics an Miscellany

Anthrax

The augmented importation of skins and hides from foreig countries as the result of the leather shortage due to the wa has caused, as one of its by-effects, an increase in anthra among those handling hides, skins and their accompanyin products, hair and wool. So serious has been the increase incidence of this disease that state and local health authoriti and the national government through the Department Agriculture and the Public Health Service are giving increased attention. The Department of Agriculture ha increased the stringency of its regulations regarding th importation of hides which may be the source of infection so that the tanners have been compelled to consider th subject especially as it affects their industry.

The Journal of the American Leather Chemists' Association for August, 1917, publishes a symposium read at the annua meeting of the association this year. After giving a description of the disease, its lesions and symptomatology, Dr. A. S Ross of Camden, N. J., says that for two years he has been practicing, as a prophylactic, the cauterization with phenol (carbolic acid) of all wounds found on employees and then applying alcohol dressings. All employees handling raw hides on pain of immediate discharge, are compelled to have all wounds, no matter how trivial, treated without delay by this method, and in Camden, where from 7 to 9 million skins are handled in the raw state each year, this method has proved effective in preventing trouble. Ross believes that if he can treat a patient within twelve hours from the first appearance of the lesion, he can save the patient. Of the three surgical methods of treating the local lesion—excision, a crucial incision and cauterization with phenol, and the injection of pure phenol around and into the pustule—Ross says that the first method is the best. On account of the extreme rapidity of the development of the constitutional infection and symptoms of the greatest gravity, the serum treatment must be employed vigorously. He uses Sclavo's serum, made from ass' blood, and Mulford's horse serum. The serum treatment employed early has reduced the mortality to 6 per cent. Ross says that in Camden he has never seen a case develop from contact with another patient, even though quarantine measures are not enforced and close contact with the patient by other members of the family is not prohibited. H. J. Frisbie, another tannery physician, endorses the excision of the pustule, cutting deep and wide, swabbing out the wound with tincture of iodin, packing with the same drug, and later applying a 1:2,000 mercuric chlorid dressing, together with sufficient doses of anthrax serum and quinin. He has had no deaths among his patients, and many of them are out in four or five days. A. Parker Hitchens describes the method of production of the serum and the manner in which it acts to immunize or cure the patient.

It has been found that the effluent from tanneries has been the means of infecting stock on streams below the plants, and on account of strict state and other regulations the tanneries have been compelled to devise means of treating or disposing of the effluent to avoid the possibility of such infection. Mr. Buswell describes the results of experiments conducted in a large tannery in the treatment of the waste by means of a screen to take out the hair and other solid matter, and the application of liquid chlorin, 50 parts per million of the screened effluent. By this means, although not all of the resistant anthrax spores were killed, they were sufficiently attenuated so that they did not kill guinea-pigs. Practically this treatment resulted in freedom from anthrax as far as infection from this tannery is concerned. C. Lee Peck describes the method employed for treating the sludge and effluent in a tannery with which he is connected. This tannery has experimented with a small unit treating 50,000 gallons of waste a day by means of sedimentation tanks, from which the sludge is skimmed and burned before bacterial action has destroyed it, the clarified effluent being spread and absorbed by the earth, no part of it going directly into any stream.

Effect of Freezing on Typhoid and Diphtheria Organisms

To determine the length of time typhoid and diphtheria organisms would live in ice cream that had been frozen solid, Bolten of the Public Health Service made some experiments which are described in *Public Health Reports*, Feb. 8, 1918. Pasteurized ice cream was placed in sterilized metal containers, inoculated with twenty-four-hour broth cultures of *B. typhosus*, and frozen in brine. After twenty-four hours the ice cream was partially melted, Endo plates inoculated and incubated for twenty-four hours. This was kept up daily thereafter for a number of days. After twenty-four hours, cultures of typhoid were fished from the plates and placed in nutrient broth and Russell slant tubes. In twenty-four hours with these cultures agglutination tests were made, with accompanying controls. One drop of a higher titer antityphoid serum was placed in the test tube and the tube incubated for half an hour at 37 C. At the end of the period all of the tubes to which the serum had been added showed a heavy flocculent precipitate. The number of colonies per plate at first was large; after ten days or two weeks there were half the number, and at the end of a month the colonies were few.

Eight specimens of diphtheria bacteria from clinical cases of diphtheria were isolated in pure cultures by plating on agar and fishing for Loeffler slants. Cultures of these were made for twenty-four hours at 37 C., washed off with 10 c.c. of 0.85 per cent. salt solution and the suspension placed in sterilized metal containers and frozen in brine. After twenty-four hours they were melted and the material inoculated in a Loeffler blood serum slant, incubated at 37 C. and again frozen. The process was repeated the following day and the cultures of the inoculated tubes of the preceding day examined. In all cases diphtheria bacilli were obtained. The freezing was continued for six days and diphtheria organisms recovered each day. Other tests failed to show any difference in toxin production between frozen and unfrozen cultures.

Veronal Classed as a Poison by England

Dec. 5, 1917, the Pharmaceutical Society of Great Britain recommended to the Lords of the Privy Council that veronal and its closely related derivatives be classed in Part I of the schedule to the Poisons and Pharmacy Act, 1908. The recommendation was prompted by the cumulative evidences, as revealed through coroners' inquests, press reports, etc., of "a steady increase in the number of fatal poisonings from veronal. . . . In addition, a growing body of testimony showed that hypnotics of this class were being widely taken in excess by the laity, without medical knowledge or supervision, with the most disastrous consequences to health and morals" (editorial, the *Pharmaceutical Journal and Pharmacist*, Dec. 22, 1917, p. 293). The Privy Council, six days later, signified its approval of the recommendation, thereby legally classifying as poisons "diethyl-barbituric acid, and other alkyl, aryl, or metallic derivatives of barbituric acid, whether described as veronal, proponal, medinal, or by any other trade name, mark or designation; and all poisonous urethanes and ureides." An immediate result will be that veronal will seldom be dispensed except on a physician's order, and that a record of such sales will be kept in the pharmacist's poison book. (The official name for diethylbarbituric acid of the British Pharmacopeia is barbitone; in the United States the designation for this product, under which it may be manufactured under license of the Federal Trade Commission, is barbital.)

Medicolegal

Sufficient Provision and Notice as to Medical Attendance

(In re Davidson (Mass), 117 N. E. R. 310)

The Supreme Judicial Court of Massachusetts, in this proceeding against a manufacturing company and an employers' liability insurance company, affirms a decree denying a physician's claim under the workmen's compensation act for services rendered by the physician in treating an employee of the manufacturing company for injuries received by the employee arising out of and in the course of his employment. The court says that the facts disclosed by the record were that arrangements had been made with a hospital to furnish to employees of the manufacturing company, injured in the course of their work, necessary medical and surgical treatment, and that notices to that effect were posted conspicuously in different places in the manufactory of the insured employer. The employee immediately on being injured was urged to go to the designated hospital. He replied that he "did not want to bother," but finally consulted a physician of his own selection not connected with the hospital. The physician contended that the notices posted were insufficient in not stating that the injured employee "must" go to the hospital. That contention was not sound. A notice of that tenor would not be true. The statute imposes an obligation on the insurer to furnish reasonable medical attendance. It does not make it imperative on the employee to accept such attendance. He is at liberty under the act, if he prefers to do so, to secure at his own expense medical attendance of his own selection. The notices posted in the manufactory of the employer were amply sufficient. They gave the name and location of the hospital where both "medical and hospital attendance" were furnished for injured employees. The decision of the industrial accident board to the effect that the insurer was not liable to the physician selected by the employee was plainly right. The insurer had done all that the act required of it in providing reasonable medical attendance.

Liability for Negligence of Intern or Other Physician Given Charge of Case

(Norton vs. Hefner et ux. (Ark.), 198 S. W. R. 97)

The Supreme Court of Arkansas, on this appeal of defendant Norton, a physician and surgeon, reverses a judgment that was obtained against him by the plaintiffs, husband and wife, and remands the case for a new trial, because of an instruction that was given the jury with regard to the defendant's liability for the negligence of an intern. The court says that the action was to recover damages for injuries resulting from alleged improper treatment following a surgical operation performed by the defendant on Mrs. Hefner, who was afflicted in a way that required a surgical operation involving an incision and entrance into the abdominal cavity. After the operation had been completed the defendant, who had come from another place to perform it, announced that he could not remain any longer, but would have to return to his home, and the question arose between the parties as to who should look after the patient and dress the wound. There was testimony adduced by the plaintiffs which tended to show that the defendant arranged with a young physician, who was acting as an intern in the hospital, to look after the patient until she recovered, and the judgment in this case was based entirely on the theory that the intern was guilty of negligence in failing to remove the gauze at the proper time, and that the defendant was liable in damages because of the alleged negligence of the intern. The trial court, over the objection of the defendant, instructed the jury, in substance, that if the defendant employed the intern to take charge of the patient for the purpose of dressing the wound and removing the gauze at the proper time, and that the intern was guilty of negligence in failing to remove the gauze properly, the defendant would be liable, and that it was wholly immaterial whether the defendant paid or agreed to pay the intern for his services. There was no testimony in the case that the defendant employed the intern, in the sense that he was to pay him anything for his services; but the evidence merely tended to show that the intern, at the request of the defendant, agreed to take care of the patient. According to the undisputed evidence, the defendant left the city shortly after the operation was completed, and did not see the patient any more; nor was there any testimony tending to show that the defendant was guilty of any negligence in the selection of the intern as a proper person to look after the patient and remove the gauze. The intern was a physician who had been selected by the hospital management to attend patients in the hospital, and there was nothing to indicate that he was lacking in qualification for the position. The evidence adduced and the instructions of the trial court presented squarely the question of whether or not a physician is liable in damages on account of negligence of another physician who takes charge of a patient at his request. That question seems to have been settled against the right to recover damages under those circumstances by a decision of this court in *Keller* vs. *Lewis,* 65 Ark. 578, 47 S. W. 755. It was clear that the instructions of the trial court as to liability on the part of the defendant were erroneous. The defendant was not guilty of negligence in the performance of the operation, or in the selection of a physician to continue the treatment after he left the city. Not being negligent in those respects, he could not be held responsible for the negligence of the other physician, who was left in charge, merely because the other physician took charge on his suggestion and arrangement. There was testimony adduced tending to establish an express agreement on the defendant's part to look after the treatment in connection with the other physician who was left in charge of the patient, and to make himself responsible for the latter's conduct and treatment of the patient; but the instructions given by the trial court did not make the plaintiffs' right of recovery depend on the existence of such contract.

Waiving of Privilege

(Jacobs vs. City of Cedar Rapids (Ia.), 164 N. W. R. 891)

The Supreme Court of Iowa, in affirming a judgment for damages in favor of the plaintiff for personal injuries alleged to have been caused by a fall on a sidewalk, says that the sole point urged for reversal was sustaining an objection to the testimony of a physician on the ground that it was incompetent for being a breach of privilege. The argument was, in effect, that the necessary relation did not exist, or, if it did, that testimony given by the objecting party and her witnesses waived the privilege. The plaintiff testified that before her injury she was in good health and able to do and doing all kinds of work. A medical witness for her said that after the injury he found an infection which must have existed before the injury; that it might not have ultimately required operation on her if she had not suffered the injury complained of, but that such injury aggravated the infection and precipitated the operation. Thereupon a physician witness for the defendant testified that he had in the past attended the plaintiff as her physician on several occasions and on each had given her medical treatment. It was contended that, as against the objection that same was privileged, he should have been allowed to say for what he gave her such treatment. A distinctive point in this case was that the plaintiff testified, "I did not consult any doctors in regard to my health before my accident." Had this been said in her examination in chief, the court would be constrained to hold that the relation which created the privilege did not exist, and this though the physician testified it did exist. Moreover, the court is of the opinion that when the plaintiff testified, though on cross-examination, that no relation existed on which the claim of privilege could rest, she settled, at least for that trial, that her objection to the medical witness for the defendant being allowed to testify was not well taken, though so far as testimony on cross-examination reveals the state of a plaintiff's health, its giving does not waive privilege. However, the exclusion of the physician's testimony did not constitute reversible error, as there was no statement of what it was believed or expected would be said if the witness were permitted to answer.

Concerning waiving of privilege, the court says that the keeping in mind of the policy and object of the statute, and that it should be liberally construed to effectuate and attain these, have developed what will *not* waive the privilege. It was the legislative intent that the patient might confide freely, and was not to be deterred therefrom by fear that this confidence would create opposing testimony. There is no punishment provided for the physician who reveals what has been confided in him. About all, then, that the statute could have aimed to do was to prevent revealing on the witness stand. It must have been understood by the legislature that those who made confidential revelations to physicians might enter into, and produce testimony in, litigation, wherein it would be very material, either as impeachment or otherwise, to have the physician disclose what he had been told, and it must have been intended, therefore, that the occurrence of these conditions should not operate to waive the privilege. It has therefore been held that such testimony is not made admissible because it will impeach, or because it will operate to defeat falsehood. And that the naked fact that the plaintiff makes a witness of one of her physicians does not give consent that the defendant may make one of any or all other of the plaintiff's physicians, and have them testify on the same general subject to which the witness of the plaintiff spoke. These cases are not inconsistent with those in which waiver arises from the nature of the lifting of the veil, and not from what sort of witness the plaintiff lifts it with. On this some narrow exceptions have been grafted, as where a physician is sued for malpractice, and the plaintiff gives her version of the treatment received; or where exclusion would operate as a shield to crime. A waiver of privilege as to one transaction will not operate to waive it as to other and independent transactions.

Basis on Which Opinion May Be Expressed as to Sanity

(Hahn vs. Hammerstein et al. (Mo.), 198 S. W. R. 833)

The Supreme Court of Missouri, in reversing a judgment obtained by the plaintiff in this action to contest a will, makes a point of the fact that a physician who had attended the testator in the few instances of his illness, and to whom a hypothetic question was put, was not asked his judgment or opinion of the sanity of the testator based on the facts observed by him during social acquaintance; for the court says that he, equally with any lay witness, might express an opinion on that subject on a statement of facts showing the basis of such opinion.

American Journal of Medical Sciences, Philadelphia

February, 1918, 155, No. 2

1 *Sociologic and Medical Study of Four Hundred Cigar Workers in Philadelphia. T. G. Miller, Philadelphia.—p. 157.
2 *Electrocardiographic Observations in Toxic Goiter. E. B. Krumbhaar, Philadelphia.—p. 175.
3 Roentgenologic Studies in Healing of Gastric and Duodenal Ulcers. W. W. Hamburger, Chicago.—p. 204.
4 *Chemical Analyses of Stomach Contents from One Hundred Pellagrins. M. H. Givens, New Haven, Conn.—p. 221.
5 *Incidence of Chronic Focal Infection in Chronic Diseases. L. Langstroth, San Francisco.—p. 232.
6 *Electrocardiographic Study of Two Cases of Nodal Rhythm Exhibiting R-P Intervals. J. D. Heard, Pittsburgh and A. E. Strauss, St. Louis.—p. 238.
7 *Pathogenesis of Infantile Scurvy; Hypothesis. H. J. Gerstenberger, Cleveland.—p. 253.

1. Sociologic and Medical Study of Cigar Workers.—The literature on the effects of working in tobacco favors the view that it predisposes the worker to pulmonary tuberculosis, gastro-intestinal disturbances, anemia, genital abnormalities, and nervous conditions. In a study of the social and medical conditions of 400 cigar workers in Philadelphia, Miller did not find support for any of these contentions. They did find, however, some wearing of the teeth and some pharyngeal and conjunctival congestion, findings which they believe to be dependent on faulty personal and factory hygiene.

2. Electrocardiographic Observations in Toxic Goiter.—Electrocardiographic studies have been made by Krumbhaar of 51 cases of goiter, mostly of the toxic type, in as many cases as possible both before and after surgical operation. In the series of 47 patients that submitted to surgical operation (ligation, partial excision, and enucleation of adenomas) 3 deaths occurred; 2 of these offered no premonitory signs in either clinical or electrocardiographic examination; in the third case the development of negative T waves might have served as an adequate warning. Electrocardiograms, essentially normal as to form and rhythm, were found in 22 cases (43 per cent.). Preponderating hypertrophy of the right ventricle (or a tendency thereto) was found in 11 cases, and of the left ventricle (or a tendency thereto) also in 11 cases. After operation, however, one half of the right ventricular cases showed a diminished degree of preponderance, whereas all but one of the left ventricular cases showed either no change or an increased amount of preponderance. Cardiac arrhythmia was found as follows: sinus arrhythmia, 4 cases; ventricular extrasystoles, 3 cases; auricular fibrillation, 3 cases; auricular flutter, 1 case; delayed conductively, 2 cases.

4. Stomach Contents of Pellagrins.—A careful review of the 100 cases examined by Givens covering over 300 analyses for acidity and pepsin, permits of the following summary: No definite relation can be found between the absence of pepsin and free hydrochloric acid, and sex, age, duration of pellagra and clinical symptoms. The gastric secretion of children is disturbed along the same general line as that of adults. Free hydrochloric acid and pepsin do not seem to be absent as often in children as in adults. Although the tendency is for acid and pepsin to disappear hand in hand, such is not always the case. It is believed that pepsin and free acid are present more often than has been expected.

5. Focal Infection in Chronic Diseases.—Reviewing his cases Langstroth finds that 84 per cent. of ulcer patients, 66 per cent. of acute or subacute cases of arthritis, 73 per cent. of the chonic cases of arthritis, and 100 per cent. of the gallbladder cases have been associated with chronic focal infections. The acute and subacute cases have responded well after removal of the foci, even to the point of absolute cure. The chronic cases, when they should be followed have in many cases had less pain and no further progression of the disease.

6. Rhythm Exhibiting R-P Intervals.—Two cases are presented by Heard and Strauss in which electrocardiographic study showed the development of transient nodal rhythm. The first case exhibited junctional premature contractions and typical attacks of paroxysmal tachycardia such as had extended over a period of twenty years; the second presented marked sino-auricular block, and under ether anesthesia there developed a paroxysm of auriculoventricular rhythm. During the paroxysms of abnormal rhythm there was present in both cases an R-P interval indicating an origin of impulses low in the conduction tissues. The comparatively rapid rates during the paroxysms of auriculoventricular rhythm suggest an abnormal stimulation of the junctional tissues.

7. Pathogenesis of Infantile Scurvy.—A report is made by Gerstenberger of a case of infantile scurvy which showed a marked reduction in the water output of the body through the kidneys without the presence of the usual and known causes for water loss via other channels, and which further showed a marked change toward a return to normal conditions by the administration of orange juice, indicating a protective salt retention of hindered salt excretion as the cause of the transfer of a good portion of the water excretion from the kidneys to the lungs. The same condition seemingly was present in four additional cases of infantile scurvy as well as in scorbutic guinea-pigs on an oat-and-water diet. It is suggested that the phenomenon observed is a part of the regular picture of infantile scurvy and represents an addition to the clinical symptomatology of scurvy. A case of infantile scurvy is reported as being counterpart to Braddon and Cooper's polyneuritic pigeons by having developed its symptoms on a diet of raw milk, modified, however, by dilution with water to one half and by the addition of enormous amounts of carbohydrates in the form of Mellin's food. The experience of other authors regarding the inefficiency of cod liver therapy and calcium therapy in scurvy is corroborated by absolutely negative therapeutic results having been obtained in a case of infantile scurvy on the administration of tricalcium phosphate and cod liver oil, indicating that a deficiency of calcium in the diet or in the body plays no primary rôle in the development of scurvy. A report is made of a distinct but temporary improvement in the clinical picture of two cases of infantile scurvy on the administration of large doses of sodium citrate. This observation suggests the possibility of the existence in the development of the clinical picture of infantile scurvy of a modus operandi similar to such as has been shown to exist in cell permeability and irritability by the researches of Jacques Loeb.

30 Improved Military Ambulance. G. W. Hawley, Bridgeport, Conn. —p. 226.

15. **Blood Counts in Noninfective Conditions.**—Fifty-one cases were studied by Meleney. These cases were chosen at random, the only cases not accepted in the series being those in which an acute infection was present before operation or a marked infection expected after it. A daily white cell count was made. In thirty-nine a daily differential count was made. In twenty-six the red cells were counted anteoperative and postoperative, and on alternate days thereafter. In every single case the white count rose six hours after operation. Nine cases were later set aside because of the presence of slight infection. Meleney says that the postoperative leukocytosis in noninfected cases is due almost entirely to the outpouring of polymorphonuclear cells. There is a trivial rise in red cells after operation, but in the subsequent ten days this is followed by a progressive anemia with an average loss of about one-half million cells per c.mm. The white cell count may be expected to fall rapidly in clean cases and reach normal on the fourth day. In infected or contaminated cases it will fall much more slowly. Infection and contamination have nothing to do with the initial rise, but on the second or third day after operation they will tend to keep the count high. Other things being equal, the count will be higher in those cases in which there are severe trauma to the tissues, many sutures and ligatures used, considerable loss of blood and long anesthesia, especially with ether. Normal individuals will produce a higher leukocytosis than abnormal types.

16. **Electric Burn Causing Necrosis of Skull.**—Lewis' patient recovered from a very severe shock, having come in contract with a live wire carrying an alternating current of 13,200 volts with an amperage of 150. He sustained an injury to the skull which corresponds to a certain definite type of which thirteen have been reported. Some eight weeks after the accident a double cataract developed rather rapidly.

18. **Bone Transplantation in Treatment of Paralytic Feet.** —The object of this operation is to secure bony ankylosis and so assure stability and prevent lateral deformity of a flail ankle, fixing it in a position of equilibrium midway between flexion and extension. This is done by Fuld by inserting a bone graft which passes through both malleoli and the body of the astragalus.

22. **Incision to Expose Lower Abdomen and Pelvis.**—The skin incision, described by Churchman, begins at the symphysis pubis, runs in the midline upward for about 2 inches, then diagonally upward and outward toward the anterior superior spine. The fascial incision repeats the direction of the skin incision, dividing the rectus sheath longitudinally, then crossing obliquely the anterior sheath and dividing the fascia of m. obliquus externus in the direction of its fibers and as high toward the anterior superior spine as desired.

26. **Fat in Appendix and Inflammation.**—Smith's work is based on a study of 217 appendices. He says that chronic inflammation of the appendix may be associated with or without an increase of visible fat. In about 14 per cent. of appendices examined which were chronically inflamed fat was very much increased and affected occasionally the muscular coat as well as the submucosa. Smith concludes that abnormal accumulation of fat in the appendix is induced by inflammation, aided probably by impairment of circulation in the wall of the appendix.

29. **Benign Ulcer and Carcinoma of Stomach.**—Forty-eight ulcerated lesions of the stomach comprise the material studied by Wilensky and Thalhimer. This includes 39 chronic ulcers, 7 ulcer-like carcinomatous lesions, 1 ulcer with regional carcinomatous lymphnodes, and 1 mixed lesion (resembling an ulcer but with carcinoma at many places on its periphery). This summary does not include 5 gastrojejunal ulcers and 2 healed ulcers which were also investigated. This investigation has not furnished absolute proof that carcinoma of the stomach can arise in a preexisting ulcer. In one specimen out of the 48 examined there was present a carcinoma arising in an ulcer. The majority of ulcerated gastric lesions, however, are either simple chronic ulcers or definite carcinomas. Any etiologic relationship of gastric ulcer to gastric carcinoma cannot be traced in these specimens. Ulcerated gastric lesions which appear benign grossly were proved by the microscope to be malignant in 18.7 per cent. of the cases studied. It is lesions of this sort which the authors claim have given rise to considerable confusion in the past. It is impossible to state whether they represent an ulcerating carcinoma or an ulcer which has undergone malignant transformation.

57. **Peanut as Food.**—The experiments made by Daniels and Loughlin prompt the suggestion that the peanut, when rightly supplemented, will form a staple article of the human dietary. Like the soy bean, it needs only to have added suitable inorganic material and the fat soluble food accessory to make it a complete food.

58. **Pellagra Producing Diets.**—Even with food mixtures derived from two to five seeds McCollum and Simmonds have not found it possible to induce any growth in young rats when the animals were given distilled water to drink, and were therefore, afforded no inorganic salt supply other than what was contained in the seeds. The elements, sodium, chlorin and calcium, are the only ones which must be added in order to make the seeds complete from the inorganic side. Iodin was given in the drinking water once each week. Millet seed and flaxseed are both distinctly better as sources of the fat soluble A than are the cereal grains, wheat, maize and oats. Mixtures of seeds containing one of these may, when properly supplemented with calcium, sodium and chlorin support animals in apparently good health, and without the appearance of xerophthalmia. Emphasis is laid on the close similarity of seeds from the dietary standpoint and the danger of deriving the diet almost exclusively from this source.

61. **High Levels of Carbon Dioxid and Alkali.**—Experiments are reported by Henderson and Haggard in which a high level of carbon dioxid and alkali, or hypercapnia, was induced. Whenever respiration is depressed by means of morphin and the alveolar carbon dioxid is raised, or whenever by the administration of carbon dioxid in the air breathed the carbon dioxid content of the blood is forced up, the carbon dioxid capacity (alkaline reserve) of the blood also rises. This rise is probably due to a compensatory passage of alkali from the tissues into the blood. Through this mechanism respiration exerts a powerful influence on the alkaline reserve of the blood.

62. **Low Levels of Carbon Dioxid and Alkali Induced by Ether.**—Etherization so profound as to depress respiration causes a rise of the carbon dioxid capacity. Light etherization such as is otherwise most effective in lowering the carbon dioxid capacity, and most harmful to the subject, loses this influence when administered with sufficient carbon dioxid to maintain the alveolar carbon dioxid at a normal level. From these facts it is clear that under ether the carbon dioxid capacity of the blood (alkaline reserve) follows and is controlled by the carbon dioxid content, and that the carbon dioxid content is in turn dependent on the alveolar carbon dioxid, which is determined by the breathing. The authors are of the opinion that these results afford final proof of the essential correctness of their views on this topic.

63. **Effects of Excessive Pulmonary Ventilation.**—Excessive pulmonary ventilation by means of artificial respiration induces not only a lowering of the carbon dioxid content but also the carbon dioxid capacity of the blood. Arterial pressure also falls and death from circulatory failure may follow. If the artificial respiration, instead of being made with fresh air, is carried on by continual reinjection mainly of expired air, so that the carbon dioxid content of the blood is not reduced, the carbon dioxid capacity and arterial pressure do not fall and the other ill effects also fail to appear.

64. **Sequence of Trauma, Excessive Breathing, Reduced Carbon Dioxid Capacity and Shock.**—These experiments show that apart from overventilation of the lungs, trauma does not cause a lowering of the carbon dioxid capacity (alkaline reserve) of the blood, even when by general traumatization and cooling of the abdominal viscera and consequent stagnation of the blood in the injured parts, failure of the circulation and death are induced. If, on the other hand, no measures are taken to prevent excessive pulmonary ventilation, the overbreathing induced even by localized manipulation of the stomach, while the rest of the viscera are protected, causes lowering of the carbon dioxid content and carbon dioxid capacity of the blood, and also of arterial pressure. If the lowering of the carbon dioxid capacity is pushed beyond the apparently critical level, between 33 and 36 volumes per cent. the disturbance of the vital equilibrium results fatally. The same duration and degree of localized manipulation administered while the subject is inhaling 6 or 7 per cent. of carbon dioxid does not cause any marked lowering of the carbon dioxid capacity, arterial pressure, or general vitality. Below the critical level for the carbon dioxid capacity, treatment by the administration of 7 to 10 per cent. carbon dioxid in the air breathed does not cause restoration of carbon dioxid capacity or arterial pressure. These results are in general harmony with the conception of acapnia as a factor in shock.

69 *Infection in Cutaneous Disorders. H. Mackay, Winnipeg, Man. —p. 173.

69. **Infection in Cutaneous Disorders.**—Mackay says that in a preponderating number of cases of inflammatory affections of the skin, diligent search will reveal a focus of infection that may reasonably be assumed to stand in etiologic relationship to the disease. Vaccines are of distinct service in combating these maladies in selected cases. The removal of the focus, together with the exhibition of an autogenous vaccine, has almost invariably given a measure of relief to these sufferers, and in many cases have brought about a symptomatic cure. Relapses will usually supervene unless the focus is eradicated.

80 Effect of High Pressures on Bacteria. W. P. Larson, T. B. Hartzell and H. S. Diehl, Minneapolis.—p. 271.

70. **Intestinal Spirochetes in Phillipines.**—Fifty stools were examined by Crowell and Haughwout, representing forty-six separate hospital cases. Of these cases, thirty-five were positive for spirochetes. There were seventeen cases which showed a concomitant infection with endameba, and scattered infections with *Trichomonas intestinalis* and the more common helminths. The patients from whom these stools were obtained were undergoing treatment for various ailments. Of the thirty-five which were positive for spirochetes, ten patients were receiving treatment for endamebic dysentery.

72. **Bacteriology of Chorea.**—Cultures from the tonsils, and from the blood and cerebrospinal fluid of acute, subacute

and chronic cases of chorea were made by Quigley. Blood cultures were made in twenty-one patients, ten of whom gave positive results. Nine gave small cocci, slightly elongated and arranged in pairs, short chains, and a few groups, in aerobic cultures. The other positive blood culture gave a gram-positive short diphtheroid organism. The cerebrospinal fluid of twenty-one patients has been cultured, with thirteen positive results. One was not subcultured. Eight of the organisms isolated resembled very closely the organisms found in the blood. Throat cultures were made in fifteen patients, and twenty-nine cultures were isolated and studied. Ten were hemolytic streptococci of variable size, occurring in long and short chains. Thirteen were green producing cocci, growing in pairs and short chains. Six were organisms which grew on blood agar as pin-point colorless nonhemolytic colonies, and resembled the organisms recovered from the blood in their morphologic and cultural characteristics, with the exception of their fermentative reactions. Eleven patients gave histories of acute tonsillitis, two of rheumatism, and one of endocarditis. Eight gave no history of rheumatism, endocarditis, or tonsillitis. None gave any evidence of syphilis.

74. **Scarlet Fever Treated with Immune Human Serum.**—During the past winter and spring an unusual proportion of severe cases of scarlet fever has come under treatment in the Durand Hospital, and the most severe were selected for treatment with convalescent serum. The blood was drawn from the twentieth to the twenty-eighth day, only such convalescents being selected as were free from all suspicions of tuberculosis, who had not been septic patients, and who gave a negative Wassermann reaction. The serums from several patients were mixed, tested for sterility, and stored, until used, in the refrigerator in portions suitable for single doses. The serum was injected intramuscularly in doses of 25 to 90 c.c., 60 c.c. being the usual dose. Commonly a single dose was given, a few times a second dose was administered if the initial one did not produce the desired effect. The injections were made into the muscles on the outer side of the thigh, usually dividing the dose between the two sides. No local or general disturbances followed the injections. Nineteen cases of scarlet fever were treated in this manner and in a few additional cases convalescent serum was combined with antidiphtheria serum in cases of scarlet fever complicated by diphtheria. The effects of injections of convalescent serum in cases of scarlet fever as observed by Weaver correspond to those noted by others who have used it. Quite constantly a fall of temperature began two to four hours after the serum was injected and continued gradually until its limit was reached in twelve to twenty-four hours. In the purely toxic cases the temperature fell to nearly normal and showed little tendency to rise again. In cases with septic complications the initial fall of temperature also occurred and was associated with general improvement, but the fever rose again and ran a course such as occurs in septic cases. More striking than the fall in temperature, was the improvement in the general condition of the patient. This was most pronounced in the purely toxic cases, but also very prominent in the septic ones. Delirium subsided, the pulse became slower and improved in quality, cyanosis disappeared, and in twelve to twenty-four hours patients who had seemed almost hopelessly sick were apparently on the road to certain recovery. Septic cases coming under treatment late do not appear to be improved by the serum.

75. **Prophylaxis of Lobar Pneumonia.**—As recent investigations in the epidemiology of lobar pneumonia have indicated that the disease is frequently acquired by transmission of specific virulent types of pneumococci from a recovered person who still harbors in the mouth secretions the organisms responsible for the disease, or from a healthy carrier of pathogenic pneumococci, it is suggested by Kolmer and Steinfield that the systematic use by the patient and those in close contact with the disease of a mouth wash of 1:10.000 solution of ethylhydrocuprein hydrochlorid or quinin bisulphate in 1:10 liquor thymolis, may serve to destroy or inhibit the multiplication of the disease producing pneumococci and thereby aid in the prophylaxis of lobar pneumonia.

79. **Antipoliomyelitic Serum.**—Nuzum and Willy have produced a highly potent immune serum in the horse by repeated intravenous injections of aerobic cultures of the poliomyelitic coccus. Such a serum contains agglutinins, complement fixing bodies and especially opsonin in high titer. Monkeys can be immunized against several fatal doses of virulent monkey-adapted virus by repeated intravenous and intracerebral injections of the poliomyelitic coccus. The serum of the horse immunized with strains of the poliomyelitic coccus obtained from human and monkey sources possesses protective and curative properties against the virus in experimental poliomyelitis of monkeys.

99. **Two Stage Prostatectomy.**—Graham reports twenty consecutive prostatectomies without a fatality, performed by the two stage suprapubic method, many of which were on patients who would ordinarily be considered as bad surgical risks, bear witness to the relative safety of this method. He says that when properly controlled by functional and other tests, it minimizes much of the risk. A preliminary cystostomy has the advantages of providing the best possible drainage, thereby affording relief of back pressure on the kidneys and an opportunity greatly to improve an existing cystitis before performing the more radical operation of enucleation of the prostate.

1. **War Nephritis.**—Fifty-one cases are analyzed by Dunn and McNee. Dyspnea appears to be an unusually prominent symptom. It is, in the great majority of cases, the most outstanding complaint, and is almost always present on admission of the patient to the hospital. Very often it is the first and earliest symptom to appear, and in only two cases was there no history or evidence of breathlessness. Breathlessness was present in thirty-four cases; swelling of the face or legs in seven cases; pains in the head, epigastrium, or back in six cases; sore throat in three cases and cough and hoarseness in one case. In association with the dyspnea, cough is frequently present, and in some instances this is accompanied by tenacious expectoration. Even though cough is absent and always in its presence, auscultation of the chest reveals the presence of râles and rhonchi; the physical signs, however, are often slight in comparison with the degree of breathlessness. In only one case was considerable effusion into the chest discovered. Hoarseness (from laryngitis) was the initial complaint of one man, and sore throat of three others. In the latter cases, apart from some faucial redness, nothing could be seen amiss. Edema, while generally present, is frequently confined to the face alone. In many cases, however, it is also present in the legs, and a few examples of general anasarca have been met with. Definite ascites was seen only once. Fever was present in six cases only, the highest being 103.4 F. Uremia ensued in four cases. The urine, when the patient is first seen, generally contains a large amount of albumin. Casts are always present in the centrifugalized sediment, but are often far from numerous. Bacteriologic examination was made of thirty-five catheter specimens; fourteen were sterile; streptococci were found in fifteen, other bacteria in six. Forty acute cases were examined by blood culture. All the cultures remained sterile, even after prolonged incubation.

The authors suggest that the high albuminuria, often without obvious blood, the absence of oliguria, the frequent rapid decrease in the amount of albumin, the predominant dyspnea, and the general healthy appearance of the patient while obvious signs of nephritis are present, give collectively a rather characteristic picture differing from that of the average case of acute nephritis at home. The rapidity with which the initial symptoms of the nephritis may subside, after admission of patients to the hospital, is remarkable. It is frequently so striking as to suggest that the mere transfer of the patient has brought about discontinuance of the circumstances which caused the disease. From a consideration of the pathologic conditions no direct conclusion has been drawn regarding etiology, but some important facts have been ascertained. The visible alteration in the kidneys which is most constant and distinctive is limited to the capillary blood vessels of the glomeruli. The absence of definitely inflammatory reaction in these structures, and the uniformity and selective distribution of the lesions, suggest that they are due to the presence, in the blood stream, or a mildly irritant agent with a special effect on the small blood vessels. The edema of subcutaneous tissue, and the vascular lesions in the lungs and the brain are probably due to the same factor. The minute cerebral hemorrhages which are occasionally present in nephritis are of exactly similar character to those which frequently occur after poisoning by phosgene. In fatal cases of war nephritis the pulmonary air passages are frequently the seat of lesions which bear some resemblance to those produced by irritant gases.

2. **Hemagglutinin Reaction.**—Bond claims that by the addition of a hemagglutinin to a liquor puris or a serum, one can induce the leukocytes to phagocytose native red cells—that is, red cells from the same blood—when incubated together. Isophagocytosis of red cells by pus cells may also be observed in pus from wounds in patients whose blood serum is hemagglutinative. Pus cells from "whole" pus (if it contains hemagglutinins of the right kind) will ingest washed human red cells more freely than washed pus cells from the same pus will digest them, although the washing in saline actually increases the activity of the cells by removing the bacterial toxins and tryptic content of the liquor puris. The difference in the two cases depends on the fact that hemagglutinins are present in the "whole" pus and absent in the washed cells. Moreover, no ingestion of red cells occurs if the "whole" pus is nonagglutinative. Putting all these facts together, Bond concludes that, so far as the phagocytosis of red cells by leukocytes is concerned, hemagglutinins also act as opsonins and prepare the red cells for ingestion.

3. **War Nephritis.**—Oliver suggests that in all cases in which pieces of shrapnel are retained in the body it would be well to have the patient's urine examined for lead. In some cases seen by him there seemed to be a distinct connection between albuminuria and retained shrapnel.

7. **Etiology of Diabetes Mellitus.**—The etiology in 300 cases of diabetes was carefully investigated by Williamson with the following results: History of prolonged great excess of sugar, sweet food, or sweet drinks (alone or combined with other predisposing causes) in 93 (= 31 per cent.). History of prolonged and intense mental anxiety, worry, overstrain, or sudden mental shock (alone or combined with other predisposing causes) in 120 (= 40 per cent.). Family history of diabetes (alone or combined) in 76 (= 25 per cent.). No definite predisposing cause in 59 (= 19 per cent.). Williamson considers it desirable for all to cut down sweet foods and drinks, chocolate, jam, sugar and alcohol to a minimum during the war, and especially for those who have a family history of diabetes, and are suffering from great mental strain or shock; they will thereby help the food controller and also diminish the risk of diabetes. Occupation and close attention to work are useful in diminishing the effects of mental worry and shock, and thereby the risk of diabetes, but in certain cases of excessive overwork it is desirable to cut off work not absolutely necessary, if this is possible; sleep is very important. The recent food restriction, as already mentioned, will check for most people any excess of sugar and alcohol, and will thus tend to diminish the risk of diabetes. Those who have been obliged through these restrictions to discontinue excess of alcohol or sugar should, however, not replace these by excess of nonalcoholic drinks containing much sugar, and excess of jam, chocolate and other sweet foods which may be still obtainable.

9. **Helpful Diagnostic Sign in Ruptured Ulcers.**—In cases of ruptured duodenal ulcer Willan has noted the presence of a transverse ring of constriction across the abdomen at the level of the lower margins of the ribs, and extending into the flanks on either side. The constriction does not always disappear with general anesthesia, although it does disappear when the condition has advanced to the stage of general abdominal distention. There is no marked hyperesthesia, and the patient is quite unconscious of any feeling of tightness at the site of the constriction. It is not confined to spare or emaciated persons, and is different altogether from the scaphoid abdomen seen in emaciation, etc. The appearance is as if an invisible rope was constricting the abdomen, dividing it into an upper portion which has a convex aspect centrally, and a normal lower part. Viewed laterally, the region of the rope forms the apex of a vertically situated obtuse angle. The ring of constriction corresponds to that portion of the anterior abdominal wall supplied by the ninth intercostal nerve, and is due to muscular contraction.

12. **Treatment of Infected Hemothorax.**—Dobson has treated cases of infected hemothorax by a method of irrigation through a special cannula which, he says, appears to be of promise. The curved silver cannula has no terminal aperture, and is perforated with twelve small holes. It is employed in the following manner: A sufficient opening is made into the chest by resection of a length of rib, preferably the eighth. Tuffier's spreader is then inserted, the pleural cavity wiped out, and perhaps a foreign body is removed or other complication dealt with. A point on the chest wall toward the upper limit of the cavity is selected where the cannula may most conveniently be introduced. This is usually in the third or fourth space, about or just external to the mammary line; a small incision is made through the skin, and the cannula pushed through the intercostal muscles into the chest. The tip of the cannula should point outward and downward, and the instrument is fixed in position by two sutures to the skin. The original incision is then closely sutured around a tube which may be long enough to reach into a bottle of antiseptic fluid. The tube of a Carrel ampoule is then attached to the cannula, and the cavity irrigated every two hours. A fine spray of fluid is thrown in every direction on to the lung and chest wall. The irrigation causes no distress; as the lung expands the point of the cannula is pressed against the chest wall and causes some pain; it should then be removed. For this reason it is desirable to insert it at some little distance from the anterior and upper limits of the cavity, otherwise it may have to be taken out before the infection is controlled. The infection is quickly controlled, the lung expands well, and the general condition of the patient improves very rapidly.

13. **Gunshot Injuries of Elbow-Joint Treated by Early Excision.**—Observation of fourteen cases has led Shepherd to the conclusion that excision of the elbow-joint in gunshot wounds offers the patient the best chance of combating the infection and of a rapid recovery with a movable joint. If excision can be performed without the removal of the heads of radius and ulna, the results are better and more quickly attained. Where possible the triceps insertion should always be preserved. The earlier the excision is performed the shorter is the illness and more perfect the result.

16. **Treatment of Chest Wounds.**—The method applied by Hutchinson in cases of infected hemothorax is as follows: As soon as a hemothorax is found to be infected the patient is taken to the operating room and nitrous oxid and oxygen administered. A portion of rib, long enough to allow the hand to be passed through the opening, is removed and the blood allowed to flow out. The clot is then removed by the hand, all parts of the cavity explored, and light adhesions broken down. Then by means of large pieces of gauze on dressing forceps the remainder of blood and clot is removed. After this the cavity should be washed out with saline and again mopped out and a running suture inserted in such a way as to include the pleura and intercostal muscles. This suture should be left quite loose, so that a small quantity of some antiseptic can be poured into the pleural cavity. This antiseptic should be spread all over the walls of the cavity by means of a small piece of gauze on long dressing forceps. As soon as this has been done the running suture is drawn tight, thus closing the pleural cavity completely. The muscles and skin are then closed and a dry dressing applied. Forty-eight hours after the operation the chest should be aspirated, thus removing a quantity of serum and air. Three or four aspirations are necessary during the course of convalescence. The antiseptics which Hutchinson has used in these cases include eusol solution, 1 in 2; a suspension of bipp in liquid paraffin in the following proportions: one-half ounce of bipp, 6 ounces of paraffin; flavine solution 1 in 5,000, and normal saline, the amount left in the chest being 3 ounces. The results obtained in twenty-nine cases treated in this manner have led Hutchinson to prefer the bipp treatment. Certain

type of infection lend themselves to this form of treatment better than others, such as *B. aerogenes-capsulatus.*

17. **Treatment of Emypema by Antiseptics.**—Stoney is convinced that most if not all cases of empyema can be cured without resort to such mutilating and dangerous operations as thoracoplasty and pulmonary decortication, because it is not necessary to obliterate the pleural space. but merely to render its walls sterile, and this is possible by frequent washings with hypochlorite solutions. Flushing of the pleural cavity with hypochlorite solution is not dangerous provided there is a free exit for the fluid, as by the use of a double drainage tube. The earlier this treatment is instituted the sooner and more surely will a cure be obtained, as there will be less formation of granulation and scar tissue, and the organisms will not have had time to entrench themselves deeply in the tissues, and will therefore be more exposed to the action of the antiseptic. The drainage should be free, and the opening should not be valvular; if a Carrel tube is used it should be introduced as far as possible into the pleural cavity through a large drainage tube, so that the fluid, starting at the most remote part of the septic space, passes down over its walls and escapes freely between the Carrel tube and the drainage tube. The opening is most sutiably made by removing 1 inch of the eighth rib in the scapular line, as this is the most dependent spot for practically all positions, and there is no fear of its closure by the rising diaphragm.

33 *Action of Acriflavine and Proflavine. W. P. Morgan.—p. 256.

30. **Wolff's Law of Bone Transformation.**—Keith urges that the orthopedic surgeon should cultivate a close observance of the behavior of osteoblasts. If he understands them fully and treats them rightly, they can prove his most helpful friends; if he ignores them, they can and do prove obstinate. In the first place, as the author has seen from their behavior in grafts, they must be subjected to stresses; stress is as necessary for their health and activity as exercise is for the living body. The mode in which they build and the lines along which they will deposit their building material are determined by the forces which are brought to bear on them. They can, by manipulating such force, be made to build as we will. They can be stimulated to overwork in many ways. By beating the external condyle of the femur with a mallet, the bone cells will build up a rampart which prevents the outward dislocation of the patella. Injury to a bone excites every osteoblast in that bone; diaphyseal growth disks act as buffers in limiting the radiation of a stimulus. Acute inflammation increases their activity and destroys their sensitiveness to pressures. The study of diseased conditions brings out other qualities of osteoblasts. In giants they become stimulated to an extraordinary degree by a certain substance or substances derived from the pituitary body; in certain forms of dwarfs this elixir of growth is withheld. In acromegaly growth is again reawakened under a pituitary derivative—a growth which chiefly affects cartilage covered areas of bone, areas which are constantly subjected to pressure and movement. Paget's disease is quite another disturbance in the life of osteoblasts. They are no longer acutely sensitive to the stresses which fall on the skeleton; they lose their engineering qualities and lay down their materials clumsily. The study of many other conditions, such as achondroplasia, periosteal dystrophy, rickets, mollitics ossium, fragilitas ossium, throws sidelights on the complex nature of osteoblasts.

32. **Preservation of Thyroid Bacilli in Stools.**—Benians' experiments support the work of Teague and Clurman, and show that if fecal specimens destined to be examined for the enteric organisms have to submit to delay in transport or for any other reason, it would be well if they were first emulsified in 30 per cent. glycerin; a positive result is then much more likely to be obtained. This is especially true in warm weather and in hot countries.

33. **Action of Acriflavine.**—Morgan found that acriflavine is, as regards both its antiseptic and toxic properties, more potent than proflavine. It has a very marked bactericidal inhibiting action on streptococci and a less marked on staphylococci, but on some other organisms its effect is practically insignificant. Its action is therefore strikingly selective. It has a marked but slow toxic action on the tissue. This toxic action of acriflavine is not so great that it should not make when used in dilute solution (say 1 to 4,000) an efficient application in a dressing for a wound infected with streptococcus or staphylococcus. It should be applied after the wound has been thoroughly cleansed by washing, first with a rapidly acting antiseptic lotion, such as neutral solution of chlorinated soda, and then by physiologic sodium chlorid solution.

37 Fragility of Heart in African Troops. A. Mougeot.—p. 12.
38 *Cardiovascular Disturbances in Typhus. J. Heitz.—p. 38.

36. **Blood Pressure in Typhus.**—Danielopolu and Simici recorded the blood pressure systematically in eighty-four typhus patients during the course of the disease and after defervescence. The maximal tension was generally found low, the minimal tension low also, but to a lesser extent. This drop in tension is due less to weakness of the myocardium than to the more or less generalized vasodilation. The latter is accompanied by extreme asthenia and these symptoms keep up and may even increase after defervescence. The asthenia persists for weeks and even months after recovery, and the arterial pressure keeps low. They found profound lesions in the suprarenal capsules, especially in the cases with particularly low pressure and asthenia. In one case of sudden death in typhus the medullary substance was transformed into a hemorrhagic pulpy mass, but some physicians have reported that the suprarenals were apparently sound in their cases that came to necropsy. Another suggestive fact is that injection of epinephrin does not induce the usual reaction. The response is less, the severer the case; there is no reaction to the intradermal tuberculin test in severe typhus, and no abscess after injection of turpentine.

38. **Cardiovascular Symptoms in Typhus.**—Heitz compares some old and recent descriptions of typhus. The fourteenth and fifteenth days seem to be the culminating *point of the* danger. Obliterating arteritis of the legs was frequent and definite lesions were often left in the myocardium.

39. **Induced Diagnostic Eruption in Measles.**—Godlewski gives a colored plate of the findings when dry cupping is applied to the chest or back for thirty, forty or fifty seconds. On 200 healthy persons there was left a whitish ring where the cup had rested. When applied to a person during the incubation stage of measles, three days before the eruption appeared, a reddish ring was seen, the skin looking as if it were stippled with red in the form of a circle. If applied forty-eight hours before the eruption, the red circle is much wider and the color deeper; twelve hours before the eruption the red circle is still wider and the color veers more to purple. This induced erythema reaches its height in three and a half minutes and then subsides, lingering sometimes up to ten minutes. This test was applied to 218 persons and the eighteen giving a positive reaction developed a typical measles eruption four or five days afterward. The subjects included children and adults; in each case there was nothing to suggest measles at the time except this ring of induced erythema. The color deepens the closer to the date of the measles eruption. Godlewski relates that ten cases of what seemed to be measles developed in epidemic form in one barrack, but this cupping glass test was negative, and the assumption of measles was disproved by the course of the cases. He has had no opportunity to apply the test thoroughly in scarlet fever, but it was negative in the two cases tested. If time and experience confirm the reliability of this reddish crown induced by the cupping glass as a sign of incipient measles, it will prove useful in camps and institutions to weed out the cases of measles without waiting for the eruption.

40. **Antispirochete Serotherapy.**—Martin and Pettit cite conflicting testimony as to the value of the serum now being made for spirochetosis icterohemorrhagiae.

42. **Influence of the Bile Salts in the Blood on the Course of Spirochete Jaundice.**—The data presented by Garnier and Reilly apparently confirm the assumption that the bile salts have a destructive action on the spirochetes. When the bile salts in the blood reach a certain level, then the septicemia stops. The various forms of the disease, the cyclic, the irregular, the transient and recurring and the abortive cases seem to be all conditioned by the variations in the excretion of the bile salts. An emulsion of liver tissue from a guinea-pig that has died from spirochetosis icterohemorrhagiae, loses its virulence when treated with a little human or beef bile or guinea pig bile. After the clinical jaundice had lasted two or three days, inoculation with the blood was always negative. The fever runs up again when only the bile pigment is getting into the blood and the active part of the bile is no longer diverted from its normal route. Definite defervescence occurs when the organism has manufactured enough antibodies to assure immunity. Otherwise the temperature keeps normal while the Hay reaction is positive; fever returns when this reaction veers to negative.

44. **Acute Gastritis in the Gassed.**—After a period of persisting nausea with vomiting and possibly hematemesis, lasting a few hours or days, there follows an acute gastritis, with pains in stomach and esophagus, and sometimes sensations of intense hunger. Vomiting and pyrosis follow immediately after eating. There may be an acute febrile gastro-enteritis for about two weeks. After this conditions may return to normal but generally the men are left with dyspepsia. They lose their appetite and feel languid and drowsy after eating, with a sense of oppression in the stomach region, and they cannot bear even the weight of the hand on the stomach region at night, but nothing objective can be found to explain these disturbances. Necropsy of the gassed, however, has shown hyperemia of the mucosa of the alimentary canal with hemorrhagic suffusions.

45. **Paratyphoid B.**—A restaurant waitress ate a can of spoiled salmon and developed an extremely grave choleriform intoxication, evidently from the toxins already in the can. The ninth day symptoms of paratyphoid fever developed. The germs had evidently required eight days for their incubation.

47. **Gonococcus Pus under Potassium Permanganate.**—Maheu has been keeping microscopic control over the urethra secretions of thirty-four men with gonorrhea who had been given a course of treatment with intramuscular injections of permanganate. In a week the number of gonococci in each islet is considerably smaller although the number of islets keeps about the same. The pus persists abundant but the nuclei of the cells show fragmentation and large macrophages follow directly after the polynuclears. The gonococci at this stage show that they are suffering.

- 48 *Suture of Old Infected War Fractures. M. Guillot and H. Woimant.—p. 217.
- 49 *Gas Gangrene. E. Job and E. Roux.—p. 233.
- 50 Hernia of Stomach through Diaphragm. P. Lecène.—p. 247.

48. **Suture of Old Infected Fractures.**—Guillot and Woimant write to extol the advantages of applying the Carrel method in cases of old bone lesions with fistulas, and also in cases of fractures several days after evacuation. They say that fully 50 per cent. of the men with fracture of the femur still have a fistula a year after the fracture unless they have been amputated. By applying the Carrel method to these old cases we not only heal them up but we avoid the functional disturbances from sclerosis, and we are able to get consolidation when this has not occurred properly. They describe the various steps of the Carrel procedure as applied to these cases, the preliminary disinfection under bacteriologic control, the operation, the sterilization of the focus, and the closure of the wound. When the cavity has to be filled up before suture is possible, they found that a graft of adipose tissue answered the purpose better than Beck's paste or other substances, as it is always available close by, and it keeps its place even if the wound gapes. Certain precautions were found necessary with it, however. The article is illustrated and the encouraging experiments with the first fifty cases thus treated are reviewed. They thus cured 70 per cent. of ten cases of fracture of the femur, that came into their hands six, ten, twenty-seven up to ninety days after the fracturing wound. The cure was complete in nine, eleven, fifteen up to fifty-one days, an average of twenty-six days. Two of the other cases are still in treatment, and one healed spontaneously. In none of the series of fifty cases was amputation required, and there were no deaths.

49. **Gas Gangrene.**—Job and Roux relate that the perfringens seemed to be solely responsible for the gas phlegmons and gas gangrene in the eleven cases they have encountered.

- 51 *Vincent's Angina. Deglos.—p. 3.
- 52 Peptic Jejunal Ulcer after Gastro-Enterostomy; Three Cases. J. Guérin.—p. 12.

51. **Vincent's Angina.**—Deglos found twenty-one cases of ulceromembranous stomatitis, Vincent's angina, among 255 men with sore throat sent to his contagious diseases hospital. The men were usually young, and the onset of the angina had been insidious, but in all there was a swollen and painful gland at the angle of the jaw on the same side, and all seemed depressed and pale. The reds usually numbered less than normal, down to 3,000,000, the whites about 10,000. Bacteriologic examination is indispensable. The "fusospirillar" symbiosis was pure in all his cases. Good

results were realized by repeated application of a 10 per cent. solution of methylene blue after clearing out the contents of the ulcer and swabbing with a solution of silver nitrate. In certain rebellious cases a single intravenous injection of neosalvarsan, 0.3 gm. in 2 or 3 c.c. of double distilled water, led to the almost complete healing of quite deep ulcerations in from four to six days. A second injection four days after the first was followed by complete recovery in eight or nine days. Otherwise the stomatitis lasted up to several weeks in some cases notwithstanding vigorous local treatment.

53 *Contracture of the Hand. R. Dumas.—p. 65.
54 Technic for Heliotherapy. Cololian.—p. 69.
55 Gardening for Convalescent Soldiers. A. Subercaze and J. Galup.—p. 74.
56 *Siphon Sterilization of the Pleura. Costantini and Vigot.—p. 78.

53. **Contracture of the Hand.**—Dumas refers particularly to what is called Volkmann's contracture. It is absolutely irreducible even under anesthesia, the trouble being a retraction more than a contracture. He explains it as a lesion of the median and ulnar nerves; this entails the temporary or definite paralysis of the extensors of the last phalanges. They become sclerosed in time as they are thus immobilized, and this is what fastens the retraction so that it can be corrected only by an operation. Treatment should be applied before this stage is reached, and the treatment required does not differ from that for any similar nervous affection of the hand. After fracture of the arm at any point, or contusion or abscess or any trouble liable to injure these nerves, the physician should bear in mind the possibility of this type of contracture, and should examine the fingers every day to see that extension occurs normally. At the slightest sign of disturbance in the sensory or motor functioning of the small muscles of the hand, all causes of compression of the nerves must be removed without the slightest delay, the cast removed, the part dressed over again. The muscles menaced should be massaged twice a day if possible, and the flexor tendons stretched repeatedly in hyperextension. At night the fingers should be immobilized on a board in complete extension. The patient should keep repeating the useful active movements.

56. **Carrel Drainage of the Pleura.**—Costantini describes the technic for application of the Carrel-Dakin method to clear out and sterilize the pleural cavity.

60 Errors in Technic with the Wassermann Reaction. Leredde and Rubinstein.—p. 77.
61 *Reduction in Normal Transparency of the Apices in Tuberculosis. H. Lebon.—p. 78.

57. **Shock with War Wounds.**—Quénu urges in treatment of shock immediate amputation if the damage is such that conservation is out of the question. If conservative measures are possible, he advocates applying some substance that will keep the tissues in the status quo, possibly preceding it with some hypertonic fluid. In this way the man could be safely left undisturbed until he had recuperated from the state of shock, and then the operation could be done under more favorable conditions. Quénu mentions that the stretcher bearers say that the wounded are seldom in a state of shock at first, that is, within an hour of the wound. The immediate shock, the nervous shock, is comparatively rare. When it is encountered, the wise plan is to defer the operation until the shock and the effects of the chilling, the fatigue, loss of blood, etc., have worn off and the blood pressure has risen somewhat. Further loss of blood should be prevented, the vessel ligated and epinephrin injected. This should be done regardless of shock, and heat applied. Probably Mencière's guaiacol solution might answer for treatment of the wound to prevent absorption from it. (The formula for this was given March 23, 1918, p. 893.) Secondary shock is always complex; absorption of septic matters is superposed on the other elements of shock. Prophylaxis of shock and the arrest of developed shock are effectual only during the immediate or primary phases.

58. **Typhus.**—Muratet remarks that no case of typhus has been known in the French and British armies since the beginning of the war to date, but Netter recently reported six cases in civilians at Paris. This shows that typhus is a constant menace, and if a person with typhus should bring the germs to the trenches there might be a serious epidemic. Typhus should be suspected by the sudden stormy onset; the fever running up to 104 or even 106 F., keeping at this height without much remissions; the small weak pulse of 110 or 120; the congestion in all the mucous membranes and the conjunctivitis, the erythematous sore throat and the presence of red spots from 1 to 3 mm. in diameter on the palate. There may be from five to fifteen of these spots the first and second day; by the third day they blanch and disappear. The petechial eruption begins from the second to the fifth day; it can be brought out by scrubbing the arm or chest or applying a ligature to the root of a member, before any general eruption. The brain symptoms may be intense from the first, but the extreme prostration is a pronounced symptom, even in the abortive cases. Inoculation of a guinea-pig with 2 or 2.5 c.c. of blood from the patient will solve all doubts. The results with serotherapy are promising. The serum is obtained from a horse inoculated with spleen or suprarenal tissue from guinea-pigs with experimental typhus.

61. **Reduction in Transparency of Normal Lung.**—Lebon expatiates on the misleading findings possible even in the normal lung. The obese and persons with thick muscles are less transparent to the roentgen rays than others; if the apical regions are not fully transparent this need not imply a bilateral lesion. The apices may not dilate evenly on both sides during inspiration, and the right apex is nearly always less transparent than the left apex. Persons who have been long in bed may have an area of dulness over each apex, and the same factors responsible for this may render the apices less transparent. The difference in the size of the bronchi aids in rendering respiration asymmetrical. Hence a slight haze over the right apex, and exceptionally over the left, is not incompatible with the integrity of the lungs. Sometimes the clavicle interferes with roentgenoscopy, and only by having the patient cough can we get a glimpse of the apex as the clavicle is transiently lowered during the cough. Examination from the rear is more instructive. A radiograph of the apex alone, taken in apnea, with brief exposure, usually is decisive; roentgenoscopy alone may not suffice. Even with small lesions, revealed by auscultation, the roentgen findings may be negative. In Lebon's experience, positive roentgen findings were always accompanied by positive auscultation signs. He warns that a haze over both apices, without stethoscopic signs, is by no means a reason for assuming a tuberculous lesion. When one apex alone seems veiled, this is much more suggestive, but even this does not justify the diagnosis of tuberculosis if the stethoscope is negative. Only when the roentgen, auscultation and percussion findings harmonize, can we regard as certain the probabilities of a tuberculous apical lesion.

62 *Shock. J. L. R. Berger and H. Vignes.—p. 49.
63 Factitious Jaundice. M. Dugardin.—p. 53.

62. **Shock in the Wounded.**—Berger and Vignes protest against the blanket term "shock" which adds an element of mystery to what is already clearly known. Instead of saying shock in the gassed, septicemic shock, shock from concussion, let us drop this vague term and speak only of the gassing, the septicemia, the condition after concussion, etc. As long as we depend on impressions rather than on carefully observed facts, there is little chance of learning the true essence of

shock and whether it is a definite entity, independent of the hemorrhage, the chilling, the pain and the emotional stress. The condition we call shock is remarkably like that from rapid anemia. The hemorrhage in the wounded is always profuse, and the intense emotion felt by the wounded, his inability to seek shelter, the pain, the chilling for hours, and the long trip on the stretcher, possibly also incipient infection—all these amply explain the difference between the condition after the simple hemorrhages of peace and the condition of the war wounded, without calling on any further morbid entities to explain the condition we call shock. Treatment should be addressed to the factors we are sure of: the chilling, the low blood pressure, with morphin and suprarenal extract, and lowering the man's head.

64 *Carcinosis of the Lung. L. Bard.—p. 1.
65 *Forms of Uremia. F. Heim and J. Tchertkoff.—p. 15.
66 *Sacral Meningocele. S. Roux.—p. 47.

64. **Cancerous Lymphangitis of the Lungs.**—Bard says that very little has been published on generalized cancerous lymphangitis of the lung, but he has encountered several cases of it. The clinical picture is entirely different from that with lymphangitis from direct encroachment of the cancer, and also from that with cancer of the serous membrane without participation of the deeper tissues of the lung. It sometimes has been known to occur isolated, without any metastatic nodule in the lungs, and both lungs may be uniformly involved. The pleuropulmonary lymphatics form a converging apparatus different from that with any other organ, and the physiologic mechanism facilitates retrograde aspiration of the lymph into the entire system of lymphatics in the lungs, and thus the extension of the malignant process. Only two cases have been diagnosed during life, and it is probable that many cases have been overlooked at necropsy. In those two cases, a man of 39 and a woman of 36 had gastric cancer; the abrupt development of râles, cough and dyspnea suggested the generalized lymphangitis, which was confirmed by the necropsy. There was some fever but not much leukocytosis. The pulmonary disturbances run a rapidly fatal course, sometimes in two or three days and never longer than three or four weeks, after the onset of the dyspnea which auscultation does not explain. Gastric cancer in the young usually runs a rapid course, with pains, and this generalized lymphangitis is one of its special features. The lymphangitis may prove puzzling if the primary tumor is not known. The rapid extension of the cancer toward the peritoneum explains the early involvement of the lymphatics. He has never encountered this generalized lymphangitis except with malignant disease of the stomach.

65. **Clinical Forms of Uremia.**—Heim and Tchertkoff emphasize the difference in the clinical picture when uremia is from retention of chlorids or from retention of urea, or there is pseudo-uremia from cardiovascular disturbance. With the latter, the symptoms are not due to retention of certain substances ingested or produced in metabolism, but they are the result of purely circulatory disturbance in the nerve centers, the arteriosclerosis in the kidneys being merely a local manifestation of the general arteriosclerosis. The clinical picture is thus pseudo-uremia. They tabulate in great detail for comparison the symptoms of these three clinical forms of uremia. The first type, tending to convulsions, chloridemia,
occurs mostly the young; the true uremia, at all ages, and
the pseudo-ure a after 40. Recovery is the rule in the first
ng ype; death is evitable with true uremia, but the pseudo-
a fcemia permits ong survival. Treatment of the first type
pains infely require striction of salt and water. In the second
of intense restrictio albuminous food and of salt, with copious
after eatine of water he third type, the pseudo-uremia, requires
for about t restrictioi fluids, with rest for body and mind, and
normal but g lly toni nd stimulants for the heart. Ten cases
lose their appcribed itail to illustrate these various types and
with a sense oible cdence. In the first type, the disturbances
lly oechanical nature from the retention of
salt and water. The disturbances in the second type, tr uremia; are essentially toxic; urea and indican are the m toxic substances to be incriminated. The third type, t arteriosclerosis type, entails symptoms resembling those true uremia, but they are merely the result of deranged c culation. It is not difficult to trace each symptom obser to one of these three types, with the indications for treatm which proceed therefrom. Detection of indican in the bl is a simple and certain means to reveal true uremia, a the writers' further experience has confirmed the reliabil of their test for indicanemia. (It was described in T JOURNAL, Oct. 6, 1917, p. 1206.)

66. **Anterior Spina Bifida.**—Roux states that an anter sacral meningocele should be suspected when an elastic fluctuating tumor, with a smooth surface, can be palpat back of the rectum or of the uterus, evidently fastened the sacrum and without connection with the uterine adne The symptoms are those of any tumor in the pelvis, co pressing the rectum and bladder. Malformation of the sacr is sometimes apparent and malformations elsewhere may gi the clue. She has found twelve cases in the literature of t last sixty years, all in women from 19 to 36 years old, whi she summarizes, and then reports in detail a case in a b of 8. The meningocele was evacuated and the opening in the spine sutured with catgut and the walls of the cyst we excised, with favorable outcome. The pressure on the rectu had caused disturbances from birth. There were never a spontaneous formed stools, on account of the "stenosis the rectum," and a kind of glove-stretcher instrument w used every day for a year to stretch the rectum. There w also some incontinence of urine during the day, never night. The internists consulted ascribed the trouble nervous factors or stenosis of the urethra, but examinati under general anesthesia revealed the anterior sacral cyst.

68 *Symptom of Atrophy of the Retina. A. Vogt.—p. 51.
69 *Tuberculous Ascites. L. Gelpke.—p. 55.
70 Ready To Use Ampules for Subcutaneous Injection. V. Kühn —p. 56.

67. Summarized in THE JOURNAL, March 16, p. 817.

68. **Ophthalmoscopic Symptom of Atrophy of the Retina.**—Vogt expatiates on the valuable information to be derive from the use of a light free from red rays in examining th fundus of the eye. He gives five colored illustrations showing the difference between the sound and the atrophied retina in this light. It is possible thus to differentiate disease in the retina and optic nerve long before the retrobulbar neuritis shows in the papilla.

69. **Tuberculous Ascites.**—Gelpke warns against removing recent tuberculous effusions. All the patients operated on for tuberculous peritonitis within two months of its apparent onset have died, in his experience with 100 cases, and similar evil experiences have been reported by Thöne at Göttingen and from the clinics at Berne, Tübingen, Bonn and Heidelberg, all the patients dying sooner or later after the operative intervention. Clinical observation and animal experimentation, he declares, seem to render it highly probable that fresh tuberculous effusions contain some curative agencies. Only the old effusions, from three to five months old, should be removed. After they are removed there follows spontaneously a new, curative effusion. At least this is the view now held by many clinicians, and to which Gelpke has been converted by his experiences since 1896 in over 100 cases.

71 *Trophic Lesions in the Face. G. Talamo.—p. 27.

71. **Trophic Changes in the Face.**—Talamo's three patients were men and women from 42 to 60 years old. The left cheek was the seat of the partial atrophy in one case, and the condyles of the jaw [illegible] st [illegible] an. She applied

for treatment of bilateral dislocation of the lower jaw. Both condyles had wasted practically away while the coronoid processes had greatly enlarged. The face had a myxedematous, waxy aspect, and there was cranial glaucoma with atrophy of the papilla. The hypertrophy of the coronoid processes seems to have been the primary disturbance. In the man, the lower jaw had enlarged. The chin during the last six months protruded forward in a peak and the condyles could be felt as abnormally small. The Wassermann test was positive in all. Talamo concludes from his study of these cases that neuritis of the trigeminal nerve is the primary cause, and that syphilis or some irritation of mechanical origin, is responsible for the neuritis.

75 Nervous Sequels of Skull Wounds. G. Dragotti.—p. 87.
76 Abuse of Tincture of Iodin. A. di Sant'Agnese.—p. 89.

74. **The Present Tasks of Clinical Medicine.**—This article is the address delivered by Ascoli on assuming the chair of clinical medicine at the University of Rome as successor to Baccelli. He emphasized that the scientific study of the sick man plus social sympathy, fecundated with a passionate love of truth and intense altruistic zeal, are bound to ensure the success of any school of clinical medicine. The modern clinic is concentrating its energies more and more on the sick man. It is growing more refined, more human, it insists on more scrupulous hospital care, and it is participating more and more in the solution of social problems. For the exercise of such comprehensive and arduous functions, the physician requires capacity and trained powers of observation in the organic and psychic fields; a wealth of scientific knowledge and a trained memory; lively imagination and a severely critical spirit; ethical and social sentiments, prompt decision and practical common sense. The practice of the profession harmonizes and balances these various elements.

Riforma Medica, Naples

80 *Iodin Urine Reaction. C. Pezzi and V. Forli.—p. 68.
81 Mouth Infection and Metastasis. B. de Vecchis.—p. 71.

77. **Specific Treatment of Endocranial plus Renal Syphilis.**—The symptoms from the diseased kidneys suggested at first that the cerebral symptoms were from the uremia, but the symptoms pointed to a tumor in the cerebellum and the positive Wassermann reaction called for specific treatment. The coexistent renal symptoms warned of the necessity for caution, but they subsided along with all the other symptoms under vigorous mercurial treatment. Concomitant kidney lesions therefore need not always be regarded as contraindicating mercurial treatment of syphilitics. It is imperative, however, to keep constant watch over the urine, and to commence with small doses.

78. **Paranephritis after Tonsillitis.**—Botteselle says that in two cases described, no other cause for the suppurating process in the adipose capsule of the kidney could be discovered except the tonsillitis just before. The patients were two young women and the staphylococcus was found in one, the streptococcus in the other.

79. **War Nephritis.**—Ceconi found a history of recent tonsillitis, acute articular rheumatism or severe chilling in a large proportion of cases of acute nephritis in soldiers on active service; in others there was pyorrhea, otitis or furuncles, but in fully 50 per cent. of the cases nothing could be found to throw light on its origin, notwithstanding its more or less epidemic character. Influenza, intestinal infection, food deficiencies and a preceding catarrhal cystitis—none of these could be actually incriminated in his cases. There is much to sustain the assumption, he thinks, that the war nephritis is a hitherto undescribed infectious disease. It seems to have been known in Russia in times of peace, and also during preceding wars. Some recent German writers on the subject are inclined to regard it as the work of the same germs which are responsible for the acute edema without albuminuria which has also been observed in almost epidemic form in some regions. The blood vessels seem to bear the brunt of the attack, and the vascular lesions are liable to retrogress completely with early and complete recovery in both these diseases. In conclusion Ceconi queries whether there may not be some connection between typhus, relapsing fever and these epidemics of acute edema and acute nephritis, besides their sharing certain factors of privations and vermin.

80. **The Iodin Urine Reaction.**—Pezzi and Forli were never able to obtain Petzetakis' iodoreaction in urine from healthy persons, or it was so faint as to be negligible, as also in most acute febrile diseases. In typhoid and paratyphoid, on the other hand, it was pronounced, and this occurred early in the disease. It thus has differential importance for the early diagnosis, while the technic is simple and easy. The reaction is often positive also in tuberculosis but it rarely happens that these two diseases are liable to be confused. To about 15 or 20 c.c. of filtered urine in the test tube are added 3 drops of a 5 per cent. alcoholic solution of iodin. The tube is lightly agitated until the reagent mixes with the urine in the upper part of the column of fluid for about 2 cm. With a positive reaction, the upper part of the fluid turns bright yellow, the tint more or less distinct but always clearly defined against the fluid below. With a negative reaction there is no change in tint.

84 *Disease of the Tibial Tubercle. A. L. Duran.—p. 17.
85 Enterococcus Otitis Media. C. J. Encina.—p. 44.

83. **Treatment and Prophylaxis of Scarlet Fever.**—Vargas has for years been treating the throat and skin in scarlet fever with a technic something like Milne's, but, he thinks, superior to the latter. When the treatment is systematically applied, the other children in the house do not contract the disease while the sick child is soothed, and rendered more comfortable. The throat is gargled every three or six hours or is swabbed out gently with a tepid mixture of 5 gm. sodium biborate; 100 c.c. of hydrogen dioxid of 10 volumes, and 400 gm. boiled water. After the gargling the mucosa is gently swabbed with a mixture of 0.1 gm. phenol; 0.01 gm. mercuric chlorid in 10 gm. each of water and glycerin. Three or four times a day a few drops of mentholized oil or phenolized liquid petrolatum are instilled into the nose. A teaspoon can be used for this if the child is unruly. Equally important is the sterilization of the skin, and for this he anoints the eruption patches with washed lard, containing 0.5 gm. thymol and 1 gm. phenol to 50 gm. of the lard. As the lard melts it absorbs more heat than other fats while the scales laden with the lard are not so apt to float about in the air. The children feel so much better from the anointing that they clamor for it. A cleansing bath is given every two days. Not only in his hospital service but in private homes with six or eight children, there has been no contagion from the primary cases given this treatment.

84. **Lesions of the Tibial Tubercle.**—Duran gives thirty-three roentgenograms. In six of his fourteen cases a detailed

roentgen study was made. Thirteen of the patients were encountered among the 6,500 patients at the public orthopedic surgery service of the Instituto Rubio at Madrid. The first symptoms had been observed from six weeks to four or five years before when he first saw the child. All complained of pain in the tubercle of the tibia, aggravated by walking or jumping and by palpation, and flexing the knee to the utmost was extremely painful. The tubercle region was always somewhat protuberant and sometimes quite hard and unduly warm, but there was never redness or fluctuation. The ages ranged from 9 to 21 and all were males except three. In five cases the lesion was bilateral, and in seven cases there was no history of trauma of any kind, and none of the patients played football or took part in other rough sports.

Violent contractions of the femoral quadriceps probably interfere with the circulation in the region, and the ossifying cartilage suffers. The consequence is an abnormal ossification of the cartilage of the tubercle, so the anomaly should be known as osteochondritis of the tibial tubercle or the tibial apophysitis of adolescents. The name of Schlatter's disease should be limited to cases of actual fracture of the tibial tubercle. Most writers agree that treatment should be restricted to immobilization with massage and mechanotherapy, but this takes from a month to two years; it has always proved successful in time. Duran preferred incising the soft parts over the tubercle for 2 or 3 cm., down to the bone, and then rapidly scraping the bone and suturing the skin. The whole procedure took less than ten minutes under general or local anesthesia, and all disturbances subsided in two weeks thereafter. He had applied conservative measures before, without benefit, and did not want to have to keep them up for a year or two longer.

Cronica Medico-Quirurgica, Havana

January, 1918, **44**, No. 1

86 *Postoperative Results of Cataract. J. S. Fernandez.—p. 8.
87 *Filaria Hematuria. R. G. Lee.—p. 15.
88 *The Cardiorespiratory Syndrome in Rachitis. C. M. Garcia.—p. 18.
89 *Starvation Treatment of Diabetes. R. G. San Martin.—p. 20.
90 Inefficacy of Autogenous Vaccine Treatment of Trachoma. J. M. Penichet.—p. 22.
91 The Glands with an Internal Secretion. A. M. Crispin.—p. 26.
92 Sclerocystic Ovaritis. E. R. de Aragon.—p. 30.

86. **Cataract Operations.**—Santos Fernandez reviews the research to date on the pathogenesis of cataract, in search for ways and means to ward off secondary, postoperative cataract. The traumatism of the operation is probably responsible for the changes in the nutrition of the parts which seem to entail the secondary cataract.

87. **Filarial Hematuria.**—Lee has encountered eighteen cases of filariasis inducing hematuria, and reports excellent results from treatment with potassium iodid. He gives it in a solution of 32 gm. potassium iodid in 60 gm. water. Before the principal meals 5 and 6 drops are taken in two tablespoonfuls of water. These doses are increased by 5 drops at a time, until the patient is taking 40 and 50 drops, under constant supervision, reducing the doses on signs of intolerance. In some cases he reached the dose of 300 drops morning and evening. All the patients were cured with the exception of one still under treatment.

88. **The Cardiorespiratory Ratio in Rachitis.**—Garcia describes a typical case of subacute rachitis in a boy of 3 in which the puzzling symptoms were explained by the abnormal ratio between the heart beat and the respiration. The ratio in this case was 2:1 instead of the normal 4:1. This is Hess' sign of rachitis, and it gave in this case the clue to the phenomena.

89. **The Skin in the Starvation Treatment of Diabetes.**—San Martin has often found that the pruritus increased during the starvation days, but it then invariably declined and sometimes it disappeared completely when the patient kept within the tolerated diet. In one case of rebellious pruriginous eczema of the prepuce for eight years, in a diabetic of 40, rebellious to all treatment, the eczema subsided during the starvation days and did not return when the tolerated diet was gradually resumed. A woman of 65, diabetic for fourteen years, had had for a year a number of congested and pigmented patches, which itched intensely and there was desquamation in some. These patches became intensified during the starvation days and for two weeks after the urine had been cleared of sugar. Then the skin returned to normal. Later there was an attack of intercostal zona with a tendency to necrosis. She reduced her diet as a precautionary measure, but there was no recurrence of the diabetic symptoms and her skin soon recuperated and threw off the herpes zoster as if full of vitality.

95 Venereal Granuloma Yielding to Antimony. A. H. Roffo and J. T. Zarate.—p. 283.
96 *Pituitary Body and Polyuria. B. A. Houssay and L. Romaña.—p. 284.

94. **Blood Cyst of the Kidney.**—Del Valle comments on the rarity of large blood cysts of the kidney. Israel reported only one in 297 operations on the kidney, and Albarran in twenty years of kidney surgery encountered only twenty-four. In a case reported, with the naked eye and microscopic findings, the man, a field hand of 48, had always been healthy until pain and swelling in the flank had attracted attention, two months before. On the assumption of an echinococcus cyst the tumor was removed through a transverse incision. The cyst was shelled out in its own capsule after incising the kidney capsule. There was considerable hemorrhage but several deep sutures were taken in the parenchyma cavity and except for hematuria for a few days smooth recovery followed. In practically all the other cases on record, nephrectomy was done, and Del Valle emphasizes the facility and good results with the technic he followed, saving the kidney.

96. **The Pituitary Body and Polyuria.**—Houssay and Romaña report the results of extensive experimental and clinical research on the action of pituitary extracts. In different concentrations and in different species they seem to have a vasoconstricting action on the kidneys sometimes, and sometimes a vasodilating action. Nothing observed sustains the assumption that polyuria is the result of pituitary insufficiency, or that the active substances—such as are found in the pituitary extracts—pass into the cerebrospinal fluid. Puncture within a small area of the base of the brain constantly induced polyuria, but not outside of this area, and the pituitary body is not included in this area. The final conclusions are against the assumption that hypersecretion of the pituitary body is responsible for polyuria.

100 *Cure of Paraplegia from Rupture of Posterior Vertebral Ligament. A. M. Perez.—p. 5.

100. **Paraplegia from Rupture of Common Ligament.**—Perez ascribes to F. Rubio of Madrid the first description of the characteristic curvature of the spine which results from rupture of the posterior common ligament. It differs entirely from the curvature with Pott's disease, etc., and there is

always a history of sudden pain in the back coming on after some extra physical exertion or trauma. One woman developed the paraplegia while dancing. Rubio's law of the morbid responsibility of the tissues links the paraplegia with the rupture, the phlegmonous focus, and the spread of this to the meninges and thence to the spinal cord. Perez gives no further differentiating points, but describes in detail a case in a young man who had been hit in the shoulder by a falling tree. The paraplegia had confined him to bed for six months but the bladder sphincter was not paralyzed. In such cases Rubio felt at liberty to guarantee a cure—like a quack—and Perez did the same, contingent on the perseverance in the course of treatment which consisted merely in suspension in a Sayre apparatus and plaster cast. He gave nux vomica in progressive doses, at the same time, to combat the tendency to paralysis in the digestive tract, with electric treatments. In eight months the man was walking with crutches, and by the end of the year was able to walk almost normally for long distances with only a light cane.

101. **Mycetoma in Argentina.**—Solari describes in detail the first case of Madura foot observed at Rosario. A fungus was cultivated from the tissues; it evidently belongs to the order of hyphomycetes.

109. **Acute Dilatation of the Stomach.**—Bolo and Gallo opened the abdomen and after removal of five liters of a blackish fluid from the dilated stomach, applied posterior gastro-enterostomy. The patient was a woman of 54 with two healthy children. The acute dilatation of the stomach developed suddenly without known cause, sudden and intense pain being the first sign of trouble. The laparotomy followed three days later. The woman vomited repeatedly in the interval, a blackish vomit.

119 *Roentgen Treatment of Eczema. E. Penso.—p. 2235.
120 Dental Dispensaries. G. H. Bisseling.—p. 2237.

116. **Osteomalacia.**—In the case described, Selhorst diagnosed osteomalacia although the pelvis seemed normal. The osteomalacia had developed in a previously healthy woman during a pregnancy and had returned during the next pregnancy. The first symptoms were pain and disturbances in the gait. Contracture of the adductors of the left leg followed. Phosphorus was given perseveringly, trusting to Latzko's positive statements that every case of osteomalacia can be cured with phosphorus, even the gravest cases. When finally all hope from the phosphorus was given up, and the ovaries were removed, unmistakable benefit was manifest. But—probably from the excessive administration of phosphorus—a hematoma and later an abscess developed in the leg, with decubitus and death in a few weeks. The general and local improvement after castration was so pronounced that Selhorst is convinced that the woman might have been saved if it had been applied earlier. The over-long use of the phosphorus evidently damaged the heart, kidneys and blood picture. This is the second case of osteomalacia published in the twenty-five years before 1913 in the clinics for women in the Netherlands, but in the three years, 1913 to 1916, twenty-three cases have been reported but none in connection with pregnancy. The history of osteomalacia is reviewed and various theories are discussed. The present conception of the disease is a return to Kilian's description of it in 1829 as being restricted to pregnant women previously healthy and of slender build. No characteristic microscopic findings have been demonstrated in any organs, not even in the ovaries, although their connection with the osteomalacia seems beyond question. Perfected technic may reveal changes which now escape us.

117. **Mammary Cancer and Marriage.**—Deelman tabulates the Amsterdam statistics in regard to the mortality from mammary cancer at various ages in the married and the unmarried since 1869. The conclusions from the data presented, as also from the 1913 report of the British registrar of births, deaths and marriages, are to the effect that mammary cancer occurs proportionately more frequently in the unmarried than in the married. At the height of the reproductive phase more married women seem to be affected than the unmarried, but, after 40, the unmarried much predominate. Nothing was found to sustain the assumption that mastitis induces a predisposition to cancer. After the fortieth year there are five married women to every unmarried woman, which readily explains the apparent predominance of mammary cancer in married women, as there are so many more of them. But calculating by percentage of each group, the predominance is altogether on the side of the unmarried.

118. **Traumatic Separation of Epiphysis.**—Hijmans gives illustrations of a typical case of traumatic separation of the inferior epiphysis of the femur in a boy of 16. The epiphysis had tilted up and lay parallel to the femur, causing the knee to bulge. Under ethyl chlorid anesthesia and strong extension the knee was flexed more and more while the loose epiphysis was manipulated until it finally sprang back suddenly into place. When the knee was straightened the epiphysis became dislocated anew, so the joint was immobilized in this extreme flexion. The plaster cast included the pelvis and the entire leg. The flexed knee in its cast was suspended by a rope and heavy weight just above the knee from an upright standard. The foot was warm; the circulation before had been somewhat obstructed by the pressure of the displaced lower end of the femur on the vessels in the popliteal fossa. By the end of the third week the upper part of the plaster cast was removed, leaving merely an open cast below the knee in which rested the leg and foot. The supporting loop of rope was moved gradually farther down on the leg which reduced the bending of the knee. Massage and exercise were then begun and by the end of the eighth week the boy was using his leg normally, and soon returned to his military academy. At first there was a tendency for the knee to keep flexed all the time, but this was corrected by laying a bag of sand on it for a while.

119. **Chronic Eczema.**—Penso has been giving from one to eight roentgen exposures in twenty-eight cases of chronic eczema which had proved refractory for from one to fifteen years to other measures. He gave a 1¼ H unit exposure and states that 50 per cent. seem to be completely cured. This represents 70 per cent. of those who returned for the entire course. He computes the cost of the salves and dressings previously used in these cases, and estimates that roentgen treatment is from 400 to 15,000 times the cheaper treatment.

Hygiea, Stockholm

121 *To Detect Simulation of Deafness. H. Nordlund.—p. 1361.

Jan. 16, 1918, **80,** No. 1

122 *Serotherapy of Scarlet Fever. C. Kling and G. Widfelt.—p. 2.

121. **Simulation of Deafness.**—The long list of measures that have been proposed to detect malingering in regard to the hearing shows that none of them is absolutely reliable. Nordlund describes fourteen methods based on speech; eleven tuning fork or similar methods, and seven methods for detecting bilateral deafness. Few attempt to simulate absolute bilateral deafness; if it is attempted, the Gowseef method or the Kindlmann method is instructive. With the former, the man's back is brushed with a brush or the hand or both. Then the investigator uses only one on the subject and the other on his own coat, brushing his own coat with the brush or hand while the subject's coat is brushed with the other. The sound and the touch combine so that the normally hearing are unable to tell whether the hand or the brush is being used on their own backs. The deaf person, not hearing the sound on the other person, is able to tell by the sensation on his own back which is being used. Unilateral deafness is tested best, perhaps, with the Lombard-Bárány method, that is, the use of an apparatus that produces a noise intermittently while the subject is reading aloud in his ordinary voice. Unconsciously he raises his voice and loses control of it when he hears the noise of the automatic drum. It may be necessary to apply a number of the tests to detect the simulation; if all give concordant results, they may be accepted as conclusive.

122. **Treatment of Scarlet Fever with Convalescents' Serum.**—Kling and Widfelt's success with this treatment has already been heralded by cable as the "triumph of serotherapy." During the last seventeen years at Stockholm there have been annually from 291 to 1,865 cases of scarlet fever, and the mortality has ranged from 1.45 to 8.63 per cent. In 1916 the disease became unusually prevalent and the death rate was 14.7 and 11.5 during two of the earliest months. Within a year there were 2,165 cases and many were of a malignant type, in both children and adults. In this epidemic they began to use convalescent serum in the severest cases, and it soon became apparent that it was effectual, but mainly in the serious toxic cases. It had comparatively little influence in warding off or curing complications. Of the 237 given this treatment all recovered except 10.5 per cent. who died early in the treatment and 7.2 per cent. who succumbed later to complications. The total mortality was thus 17.7 per cent. while the mortality in a corresponding group of 91 severe cases not given serotherapy was 70 per cent.

In the severe toxic cases, the patients in delirium or stupor when the serum was injected towards night, it was almost impossible to recognize the patient in the morning, as he was lively and sitting up and feeling almost well. The convalescents seeing this remarkable change for the better in the sick given their serum, gave their blood gladly for the purpose, the adults first, and the children followed their example without fear. It seemed to be immaterial whether the attack had been a mild or severe one; the serum from all seemed to be nearly equally effectual, but some difference was apparent in the date when the serum was taken. Good results were obtained in 70 per cent. of the convalescents' serums from the fourth week; with 58 per cent. at the fifth week; 65 per cent. at the sixth week, and 60 per cent. at the seventh week. Of the 186 convalescent serums, 111 were used alone; the other serums were mixed. Over 93 per cent. recovered of those treated the second day of the disease; all of the three treated the first day; 88.8 per cent. the third day; 76.9 per cent. the fourth day; 50 per cent. the sixth; all but one of the eight treated the seventh day, and the one patient treated the ninth day, but the one treated the tenth day died.

The serums were generally 1 or 2 weeks old when used but sixteen effectual serums were 3 weeks old; six, 5 weeks; three, 6 weeks; two, 7 weeks, and three, 8 weeks old. The blood was drawn from a vein in the back of the arm, a lightly constricting band applied above, the donor opening and closing his hand to promote the flow and the arm massaged besides. The blood is drawn into an Erlenmeyer jar with a capacity of 500 c.c. By this means it is easy to obtain through a large puncture needle 200 or 300 c.c. from an adult, with children 200 c.c. was the limit. This generally yields on standing for forty-eight hours from 50 to 150 c.c. of serum. It is distributed in vials of 25 c.c. capacity, and phenol is added in the proportion of 0.5 per cent. This was calculated by using a 5 per cent. solution of phenol and adding one ninth of the volume of the serum after 1 c.c. has been taken for the Wassermann test. The serum in question is tested further to ensure its sterility, both with bouillon and agar cultures. A positive Wassermann reaction was obtained in ten of the 196 serums tested. The vials of the prepared and tested serum are plugged with a rubber stopper and set on ice till needed.

A number of other data of various kinds are tabulated for comparison, and several typical cases described in detail. One case was that of a young woman with temperature of 105.8, pulse 140 to 160 and weak, delirium and cyanosis. The serum was given the second day after the stormy onset and the next day the general condition was transformed, the temperature normal, pulse down to 84. Typical desquamation followed in about two weeks. Before the serotherapy, 50 per cent. of cases of this kind terminated fatally. In 101 of the 195 cases proceeding to recovery under the serotherapy the temperature dropped rapidly in this way and the general condition showed remarkable improvement. The effect was similar but less rapid in fourteen other purely toxic cases. In the eighty cases with complications, this rapid success was never observed, the benefit becoming only gradually evident. One of the tables compares the mortality in the complicated cases without and with serotherapy, the percentage being with lymphadenitis 17.7 and 2.8 per cent.; with otitis media, 15.5 and 0 per cent.; with mastoiditis, 4.4 and 1.4 per cent. With seven cases of nephritis in the untreated, the mortality was 2.2 per cent., while in the forty-four cases in the treated group, 3.1 per cent. died. The proportion of cases with complicating nephritis was 20.7 per cent. in the treated group, and 21.5 per cent. among the 1,928 not given the serotherapy. The serum was injected by the vein alone in some cases, in the others, both intravenously, intramuscularly and subcutaneously.

123 *Treatment of Contracture of the Elbow. H. Abrahamsen.—p. 45.
124 Living Expenses of Average Danish Family. P. Heiberg.—p. 56.

123. **Contracture of the Elbow.**—Abrahamsen refers to flexion contracture from cicatricial shortening of the soft parts or contracture from overlong immobilization. A foreign body irritating the biceps or its innervation may entail contracture, as also a neuroma on a sensory nerve inducing reflex disturbance. In one such case removal of a bullet at the median margin of the biceps cured the contracture flexion of 90 degrees in the elbow. The most favorable position for a stiff elbow is a right angle. He remarks that about 33 per cent. of all the wounded have been wounded in the arm, and the functioning of few joints is so indispensable as the elbow. Early use of the elbow to ward off ankylosis and contracture is now the accepted principle in treating wounds in this region. When contracture is already installed, cautious correction under general anesthesia, followed by a cast, may be indicated. It is better to proceed gradually and not attempt to make the entire correction at one sitting, but waiting a week or two before resuming the attempt. He warns against forcible correction as this may arouse old troubles or induce local hemorrhage. Four cases are described in detail; one shows the fine result that can be obtained sometimes with persevering conservative measures alone. This case also teaches the danger of waiting too long before exercising the arm after a fracture. A splint was worn for six months. In a second case all that was necessary was to sever the cicatricial tissue at one point. The other cases required plastic lengthening of the tendon.

ANGINA PECTORIS[*]

E. FLETCHER INGALS, M.D.[†]
Professor of Diseases of the Chest, Nose and Throat, Rush Medical College; Professorial Lecturer in Medicine, University of Chicago

WITH THE COLLABORATION OF

WILLIAM R. MEEKER, B.S.
Associate in Anatomy, University of Chicago

CHICAGO

I do not know of any greater service I can render the fellows of this institute and the public than by considering, from a very intimate acquaintance, the time-worn affection that forms the subject of this article. I cannot hope to add much that is new, but I confidently hope to call attention to vital points that may have been overlooked by some practitioners, though of the highest importance to sufferers from this malady.

Just at the beginning of the world war, Sir Clifford Allbutt published an exhaustive work on diseases of the arteries and angina pectoris, in which he presents many arguments against some of the long-accepted views on these subjects. But the very comprehensiveness of the two large volumes places the matter far beyond the time limit of the average practitioner, and almost beyond that of the specialist devoted to diseases of the circulatory organs. A careful study of Allbutt's work and an analysis of sixty histories of angina pectoris, out of the 1,396 cases of heart disease that I find among my records of private patients (exclusive of all dispensary and hospital cases) has considerably modified the views I formerly held on this subject. Many of the patients were seen in consultations with other physicians or came to me from a distance, so that I saw them only once or twice. In most of them I did not learn of the final result, and in very few, because of their being private patients, have I been able to see the pathologic changes. Allbutt has been able to make extensive studies of pathologic changes in this disease; therefore I cannot speak with assurance on points when my former impressions do not coincide with his; but from the clinical standpoint alone I feel confidence in my own observations, and the views I shall present in this paper seem to me sustained by the facts.

SUBJECT AND DEFINITION

Angina pectoris is a paroxysmal painful disease of the circulatory organs in which the pain is usually located near the base of the heart, over the large arteries and in the shoulders, neck and arms, most frequently confined to the left side, but often in the right side. It is often attended by dyspnea and commonly by mental depression or a sense of impending death, which must not be confounded with fear. It is questioned whether the group of symptoms attending angina pectoris should be dignified as a distinct disease, especially since the pathologic findings vary in different cases; yet the variation is much less than in many other affections recognized as morbid entities, so called.

Most authors also recognize pseudo, false or mock angina, which is of nervous origin and commonly associated with intercostal neuralgia. This is much more common in young people than in old, and more frequent in women than in men, although only three fifths of my series of cases were in women, which is a much smaller proportion than I had supposed. It is not a serious affection, although the symptoms are not very different from those of true angina. A careful distinction must be made between these purely neurotic manifestations and mild attacks of true angina associated with diseases of the arteries or of the heart. The neurotic or vasovagal cases are not angina pectoris, although many cases commonly classified under this head are really true angina. Indeed, most cases of so-called pseudo-angina are manifestations of the true disease. Out of sixty cases I observed, twenty-eight were classified as pseudo-angina and thirty-two as true angina; but in the absence of pathologic demonstrations I am inclined to think that in some of them my diagnosis was at fault and that they should have been classed as angina minor, that is, mild attacks of the true angina. Pseudo-angina thus appears to be much less frequent than was formerly supposed.

Many authorities recognize angina sine dolore, which is accompanied by paroxysms of cardiac dyspnea, and is usually quickly fatal, but not attended by pain, or at least, not by severe pain. This is quite different in its manifestations from the angina with which we are most familiar. It is considered by Balfour as one of the manifestations of true angina pectoris; and its frequent appearance in persons who at times suffer from severe paroxysms of cardiac pain with a sense of impending death, together with pathologic findings, support Balfour's view.

The commonly accepted views of the frequency, etiology and prognosis of pseudo-angina, true angina and angina sine dolore, I think, would be changed by a careful study of the evidence presented in this work. Such a study, I feel, would make clinicians more careful in their diagnosis and more helpful in their treatment of patients.

---

[*] Read before the Institute of Medicine of Chicago, March 28, 1918.

[†] The material for this paper was gathered by Dr. Ingals during the past summer; but on his becoming exhausted and being required to take a complete rest, he secured the assistance of Mr. Meeker, who arranged the material in readable form.

MORBID ANATOMY AND PATHOLOGY

True angina is generally supposed to depend on disease of the coronary arteries, causing their contraction or obliteration and thus interfering with the nutrition of the myocardium. But if, as held by some observers, it more commonly results from disease of the aorta or possibly of some of the other arteries, we can more readily understand the diverse seats of pain and we can better realize why very often the heart is not at all disturbed even by most severe attacks. Myocardial disease is not essential to angina pectoris, although it is present in many cases. It also seems proved that angina does not occur in the majority of cases of coronary occlusion.

As for the mechanism by which the pain is brought on, it is probably due to excitation of the nerve end organs in the sheath of the ascending aorta and other large arteries. It is the kind of pain that belongs to fibrous tissues.

PREDISPOSING CAUSES

In my series of thirty-two cases, four were under 30 years; five between 30 and 40; six between 40 and 50; seven between 50 and 60; seven between 60 and 70; two between 70 and 80, and one of more than 80 years. It is thus more common between the ages of 50 and 70. It is more common in men, as may be seen by my series which included twenty men and eleven women. The use of alcoholics, tobacco and coffee predisposes.

It is asserted that syphilis is a factor, especially in those under 45 years old. Typhoid, rheumatism, gout and influenza predispose in patients of more than 45. In some mild cases in which the patients seem to be benefited by exercise, it is probably of gouty origin. In those past 50 years of age, arteriosclerosis and high blood pressure, especially if associated with diseases of the aorta, are etiologic factors. It also occurs with mitral stenosis, thrombosis and pericarditis. Angina pectoris and aneurysm are often coincident, but the angina frequently appears a long time before the discovery of the aneurysm.

Occupation.—It is a curious fact that out of thirty-two cases classified as true angina pectoris, nine were in physicians, or nearly 30 per cent. I saw two others that were not included in the list because they were not my patients. I attach no significance to these figures because I do not know why I was consulted by so many physicians; but they serve to emphasize the danger of drawing conclusions from incomplete statistics, and are at least suggestive as to syphilis as an etiologic factor.

EXCITING CAUSES

Some vasomotor disturbance, worry, muscular effort, or annoyance of any kind may bring on an attack. Pain frequently comes on during or after a meal, especially breakfast. Minor attacks of angina are brought on in the same way as the more severe. Only a few cases seem due to a single effort, but two of my cases certainly started in this way, and in X, whose history follows, the first distinct substernal pain was brought on by a rapid walk.

Among the various hypotheses regarding the origin of angina pectoris are distention of the ventricles, cramp of the heart muscle, myocardial ischemia, obstruction and spasm of the coronary arteries, and neuralgia, or vasomotor storm.

The coronary disease is considered a cause by most physicians, but it has been found that a large percentage of those with coronary obstruction have not suffered from angina pectoris. If the process i gradual, a patient may live with 75 per cent. of th coronary lumen occluded, or even with complet obliteration. The spasm hypothesis also seems untenable, though a sudden obstruction of the coronar arteries may cause pain like angina pectoris. In man cases, even though the coronaries may be obstructed the myocardium remains practically normal. Blocking of the coronary arteries causes dyspnea but ofte no pain. In a large proportion of fatal cases of angin pectoris, no obstruction of the coronaries is found but in most fatal cases there is some change in th coronary arteries and myocardial degeneration. Thes changes, however, are not the cause of the pain, bu are one of the chief factors of death during the disease. Often the rhythm of the heart is unchanged an the blood pressure is not affected by the painfu attacks.

As to the immediate cause of the pain, there ar convincing arguments to show that it is not due t cramp of the heart, to distention of the left ventricle or to undue systolic effort. The experience of X leads me to coincide fully with these views. The pains seem to result from an exalted state of the sensory paths, which appear to be along the aorta and larger arteries. Arteries, whether inflamed or not, are capable of pain, as shown in embolism and on compression for aneurysms, and angina is usually the result of inflammation in the aorta and larger arteries. From his own sensation, X feels that much of his pain comes from this source, as indicated by the sudden feeling of distention and by the location of the pain. The suprasigmoid portion of the aorta is probably the most sensitive, angina resulting when the fibrous outer investment is reached. The fact that the use of iodids sometimes stops the horrible pain of aneurysm, and also often stops pain in angina, indicates that the pain in these two affections may be due to the same cause. Tension of fibrous structures in any part of the body may cause pain, and this tension is the principal factor in angina pectoris. At the base of the heart there is most likely a point of exalted sensibility to blood pressure. Perhaps all arteries have their degrees of sensibility to blood pressure.

If, as maintained by some, the disease results from an affection of the coronary arteries with degeneration of the myocardium, it is difficult to understand why the heart's action is commonly almost normal, and why the pain usually referred to the precordial region is commonly felt over the aorta and radiates along the course of the larger arteries. The theory that the real seat of the disease is usually in the arterial walls and often in the external coat accounts for the incidence of the pain much better than the older theory.

SYMPTOMATOLOGY

The physical signs are not characteristic, but often there is moderate enlargement of the aorta and enlargement of the heart in many cases. There may be an aortic murmur and the rhythm of the heart may be affected, but all these symptoms may be absent.

The blood pressure may be excessive, but usually it is not affected. The pulse commonly remains nearly normal, but often, although regular, it may run as low as 40 or 50, and it has been observed as low as 21 per minute. I recall three cases of abnormally slow pulse seen at nearly the same time with nothing in common but the pain.

Profuse sweating is not an uncommon symptom, and salivation occasionally occurs.

Fever may sometimes be present from the acute aortitis. The face may be pale, flushed or normal.

There may be restlessness and tremors.

Flatulence and gaseous eructations are generally present.

Dyspnea is not a characteristic feature, but when the heart muscle is weak, it is likely to be present.

The pain in angina is usually paroxysmal, rarely a steady grind. It may increase from slight to extreme anguish. It may be short and sharp for an instant only, but it usually lasts from several minutes to half an hour or more, and occasionally continues much of the time for days. Sometimes it is confined to the chest; at other times it radiates to one or the other arm, rarely to the thigh. It is located sometimes in the neck and occasionally in the throat or larynx. It is sometimes felt on the radial side of the arms and may run down to the thumb. In some erratic cases, the pain may be confined to the periphery, as to the palm of the hand, or to a finger, and in one of my cases it was often felt in the rim of the ears. It may also be felt in the epigastrium, the apex of the heart or the abdomen. There are some cases in which the patient has a horror but an absence of pain. Angina without pain (angina sine dolore) is comparatively rare, but may be the cause of death in many of those who die suddenly without symptoms.

The heart pain in angina pectoris is usually said to be precordial; but in reality it is nearly always felt at the upper part of the sternum over the aorta. In one case that I have observed, it started in the region of the left subclavian and was so constant that the patient, a physician, believed there was an aneurysm of this artery. With X it usually started over the brachial artery in the middle of the right arm.

When the aorta is the seat of the lesion, the pain on exertion is likely to radiate to the shoulders, and it generally extends down the left arm, the reason for which proceeding is not apparent. It is sometimes relieved by eructations of gas, and such cases are very likely to be attributed to indigestion. In a few instances paresthesia or even paralysis of the arm follows the attack.

Immobility from a fear to move, or a feeling that one cannot move, is a common symptom. The feeling of impending death or of horror is not a reasonable apprehension, nor yet a fright, but an organic sensation, a feeling as though everything was going and nothing mattered. It may occur in only one or a few of the attacks, and sometimes is altogether absent.

The history of a single case illustrates most of the features of this disease so well that I will present it briefly at this point.

REPORT OF CASE

When 63 years of age, Dr. X suffered a comparatively mild attack of typhoid fever in which the temperature never exceeded 103.5 F. He was not delirious, lost only about 30 pounds in weight, and was confined to his home only three months. He had suffered from no infection nor sickness of any kind for forty years, although since boyhood he had often had rheumatic pains on exposure, and for about fifteen years had gouty pains with enlargements of the joints in one finger after another, each joint remaining tender for about eighteen months. This was a hereditary condition. His parents lived well on into the eighties, and of five brothers and sisters of which he was one, all are still living, the youngest being 55 and the oldest 72 years of age; and all are well except for a chronic gouty condition of the fingers.

Three or four days after leaving his room, he was able to go to his office for an hour daily. For several months he was troubled a good deal with dyspnea, on walking or attempting to carry even light weights. Gradually he regained strength and experienced no pain in the chest until after a brisk walk of about 500 yards in the autumn when he was 64 years of age. When he rested a little and walked slowly this pain subsided, but did not disappear for about twenty minutes. For several years he suffered frequent pains at the middle of the arms directly over the brachial artery, usually on the right side, and occasionally an aching pain in the elbow. The one in the right arm was especially severe sometimes shortly after breakfast or after exercise. These pains he attributed to rheumatism, as they usually occurred with changing weather or whenever he was chilled. He worked hard, but was very temperate in his habits, using no alcoholics, tobacco or coffee, and very little tea. His appetite and digestion were good, and he regulated the amount he ate so as to keep his weight down to the average for his size. He had no pain that he recognized as angina pectoris until the middle of May, 1913, when 64 years of age. For a few days he had found himself getting out of breath easily, and one night while in bed he had a distinct attack of angina pectoris, though not severe enough so that he called any one.

After this, the pain over the aorta came with increasing frequency and severity, so that within a couple of weeks he decided to go to Nauheim, Germany. But while waiting for a steamer he went daily to his office, where he lay on a couch most of the time directing the work of his assistants, unable to walk more than 4 or 5 paces without bringing on the pain. During these four weeks he at times took aspirin to relieve the pain, and several times tried nitroglycerin, but without any relief, probably on account of the fact that the preparation was too old. He also tried amyl nitrite, but without much satisfaction. He took no opiates, as they always disturbed his digestion.

He arrived at Nauheim very weak and unable to walk for more than a few yards without pain. There he took the regular cure of baths, went about all the time for six weeks in a wheel chair, rested an hour and a half or more every day, and had gentle massage of evenings. He felt so cold most of the time that he wore a heavy ulster and was wrapped in blankets all summer long, whenever he was outdoors. After his six weeks' course of treatment, he could walk slowly about 50 feet before the pain would compel him to stop, and after a few minutes could repeat the exertion. He gradually regained strength, so that on his return in the fall he could walk slowly for from 50 to 75 yards on a level, according to the weather, the temperature, etc. A few months later he discovered that fresh hypodermic tablets of nitroglycerin dissolved on the tongue would relieve the pain in two or three minutes, although they might cause dizziness and headache. The same tablets swallowed would not give relief for about ten minutes, and then only about half as much as when dissolved in the mouth. As sodium nitrite and erythrol tetranitrate quickly caused disturbance of his stomach, they could not be taken. At Nauheim he was advised to take theobromin, 15 grains, three times a day; but as he was very sensitive to all medicines, he took only 5-grain doses, and this only five or six times, as it greatly increased the heart pulsations and intermissions. Caffein appeared to make him worse. Strychnin or nux vomica kept him awake, and doses of digitalis sufficient to reduce the pulse to normal seemed to make his pains worse after a short time.

During this period the heart intermitted several times a minute, and the pulse usually ran from 85 to 120. The blood pressure was about 130 to 140 and never was found more than 148.

In the beginning of the disease, X, judging from the suddenness and location of the pain and from the feeling of distention, felt that the trouble must be in the arteries, although he found no confirmation of this theory until he read Allbutt's work four years later. Allbutt argues that pressure on an artery, as in treating aneurysm or an[illegible]olus, causes acute pain. X found [illegible] sleeping f[illegible]hour or two on the right side he would sometimes waken with acute pain in the right arm, which would quickly be relieved by his taking nitroglycerin. This seems to support the arterial theory, for there had been nothing during this sleep to disturb the heart except the weight of the body pressing on the right arm. The excessive fatigue which he experienced at times, however, even with no unusual exertion, points sharply to myocardial degeneration.

As the anginous pains came just as the thumb joints were recovering, he suspected that they were of gouty origin, and therefore, for about two years, gave up the use of meat almost completely. Frequent experiments convinced him that the white meat of fowl was to him as injurious as beefsteak or roast beef. Later, on account of the weak myocardium, he returned to the use of meat in moderation.

The pains in this case were brought on by a variety of conditions, such as walking at an ordinary gait on a level, climbing a very slight grade, going up four or five steps, or feeling moderate excitement, pleasurable, or more particularly annoying. A moderately full meal or the act of putting on his shoes after eating, or even of brushing his teeth, or of reaching up to take down his overcoat, or of being in the slightest hurry were all followed by pain.

The sufferer from repeated attacks of angina is usually worse in cold or stormy weather. The latter is not necessarily the result of chilling, for it may and often does occur while the patient is in bed in a warm room. It is apparently due to the subtle meteorological conditions heralded by the pains in chronic rheumatism for hours before an approaching storm.

In the case of X, attacks were brought on by a chilling of the surface, by even slight changes of weather, and once by a wind storm that he encountered when traveling in a warm car. During the blizzard early in January, 1918, X suffered continually for about forty-eight hours with severe angina pains in or under the lower part of the sternum, and in the stomach and arms, when he was not under the influence of large and frequently repeated doses of nitroglycerin. The remedy seemed to be losing its effects, but these pains finally subsided under the influence of heat applied by means of an electric pad, which was kept hot for about twelve hours. During this time, it was sometimes necessary for him to take three or four doses of the nitroglycerin in the course of fifteen minutes, in order to be able to eat even a very light meal. The pain did not return with any severity for several weeks. It often came on while he was eating or addressing a company of his fellows. Indeed, almost anything that increased the rate of the pulse for a few seconds seemed sufficient to cause the pain in the arms or through the shoulders. The same exciting factor carried a trifle further brought the pain over the aorta, or if carried still further, brought on that awful horror which is spoken of as the sense of impending death.

During the pain, even though it was not very severe, he was afraid to move lest it be greatly increased, and once although the nitroglycerin was only 4 or 5 feet away, he hesitated some minutes before he could nerve himself to get it. He carried the tablets in a closely stoppered half-dram bottle in the pockets of every suit, and always had a bottle within easy reach of his bed.

By riding a light motor wheel, he was able to play golf during part of each of the last three summers; but on the days he played, he had to take from ten to twelve 1/100 grain tablets in the course of a couple of hours. He found that frequently on the day after playing, he had no pain, whereas usually he had it several times a day.

In two years, he took three courses of saline baths of the same content as the bath most used at Nauheim. The most important feature of his treatment was an afternoon rest in for about two hours daily, with from eight to nine hours' night, his daily work being limited to five or six After the trial of many medicines, he settled down cerin as often as needed, taking usually four to day, and twice daily arsenous oxid, 1/21 grain with extract of digitalis, 1/4 grain, extract of nux vomica, 1/4 grain, and 1 1/8 grains of chlorbutanol to prevent insomnia. On this plan he has been able to continue his work in the past two years. He feels the pain often and has to take rather more of the nitroglycerin than formerly, but thus far he has found that it relieves the pain very soon if used in sufficient quantities. Recently, apparently on account of an unusual strain for a few seconds, the heart compensation broke, and he was obliged to take a prolonged rest. In spite of the rest, the pains have increased in frequency.

DIAGNOSIS

The diagnosis is usually based on substernal pain radiating to the arm, shoulders or neck, accompanied by a peculiar mental depression or a sense of impending death, aggravated by exertion or even by slight movements; but it may come on, as in the case of X, even during sleep. We should always suspect angina pectoris when pains result from exertion, no matter what their seat, especially in the aged or the syphilitic. The pain is often attributed to indigestion, but we must be suspicious if it is excited by exertion. I have known several men about 65 years old who, while apparently in excellent health, have been suddenly attacked with what the first physician to arrive termed acute indigestion; yet within a few minutes or at most a few hours, they were dead of angina pectoris. I have observed similar cases in which life has been saved by prompt and judicious treatment. When physicians realize that the pain of angina is seldom in the heart as usually described, but that it is commonly under the sternum or along the course of the larger arteries, so that it may even be in the stomach or bowels or other remote parts of the body, such errors and catastrophes will be much less frequent. If we have been taught to expect pain only over the precordia and down the left arm, we are apt to miss the significance of a pain over the upper part of the sternum and in the right arm, and we are much more liable not to recognize the disease when the pain happens to be centered in the epigastrium or even over the lower part of the abdomen.

The relief of pains by nitrites is considered a diagnostic feature; but this is not necessarily the case, for the nitrites do not always give relief, even under the best conditions. It must also be remembered that the nitrites are not effective when the preparation is old. The pains of pseudo-angina are relieved by the nitrites, and it is probable that still other pains may be relieved by these remedies, just as bronchial asthma is often promptly relieved.

It is asserted that angina pectoris in persons under 45 is usually of syphilitic origin. Possibly this is the explanation for the benefit that has sometimes been obtained from arsenic and the iodids. The value of a syphilitic history as a diagnostic point, however, cannot generally be relied on, as very few private patients will admit that they have had the disease if they can avoid the admission.

In pseudo-angina, the symptoms are much like those of the real disease; but the jactitation and absence of that awful feeling of impending death (I do not mean fear of death), together with the history and the position of the pain, usually make a diagnosis reasonably certain. I think that with many of us the crucial test has been found in the result. We have been accustomed to consider that the patient who recovered had an attack of pseudo-angina, whereas we are ready to admit that the one who died had the real thing.

PROGNOSIS

In the milder forms of the disease, suitable care and treatment may prolong life possibly for many years. For myself I know that I had come to think that with real angina pectoris, the first, second or third attack was almost sure to be fatal; but a careful analysis of my own sixty private cases and especially the experience of X, who, several times a day for four and a half years, has suffered more or less severe attacks, many of which might have been serious but for the means of prompt relief, have greatly modified this view. I unfortunately have not the end-results in many of my cases; but of the twenty-eight cases that I classified as pseudo-angina, three patients had already lived four years when my last notes were entered. Of the thirty-one cases in which I had no doubt about the reality of the disease, two patients had lived from one to two years; 3, two years; 4, three years; 4, from three to four years; 1, five years; 1, eight years; 1, twelve years; 1, fifteen years, and 1, thirty years. This would seem to indicate that those with true angina had outlived the pseudo-angina; but as I have records of death in only four cases with true angina and none in pseudo-angina, the figures have no significance as to end-results. They do show, however, that true angina is not nearly as hopeless as we are wont to believe, and that not a few may live to comparatively old age.

Allbutt makes a more hopeful prognosis than most authorities. This should be comforting to those who have experienced the pains and the awful mental depression that accompanies them. He thinks there is no close relation between the danger and the severity of the pain, but the degree of "angor" is the most ominous symptom. Without angor, angina minor may last for years or may even disappear. One of our fellows who had the pains often a few years ago is now quite free of them, although not young, and is very active in his profession. I have seen cases that lasted more than ten years, and I knew intimately one woman who suffered for thirty years, having at times very severe attacks. The celebrated John Hunter suffered from angina pectoris for twenty years before he finally died in an attack. During the four years, X has improved much in some respects, and if he can maintain a corresponding rate of gain for the next fifteen or twenty years, he hopes to be well.

In the majority of fatal cases, death is due to inhibition of the vagus, stung by pain. A fall in blood pressure resulting from mitral disease or from administration of nitrites relieves the vagus and saves life. An aortic murmur in syphilitic cases is of grave importance, indicating rapidly progressing changes. There are no physical signs that aid much in determining the probable duration, except that weakness of the heart sounds is indicative of myocardial changes, which add greatly to the danger. A sound heart can free itself from vagus arrest, but an enfeebled heart may fail. Chronic aortitis may suddenly end in angina pectoris.

TREATMENT

Nitrites are among the most valuable remedies, but they are commonly given in insufficient doses. X found the most satisfactory preparation a hypodermic tablet of nitroglycerin of 1/100 grain, which was found to act more promptly and effectively than otherwise, when allowed to dissolve on or beneath the tongue. In this way its full effects were experienced in from one to three minutes, whereas, if it had been taken into the stomach, only about half the efficiency was experienced, and it did not appear for about ten minutes. Frequently two or more of these tablets were taken at once, and they were repeated every few minutes until the desired effect was obtained. Often as many as ten or a dozen were taken in two or three hours. As much as 15 to 20 hundredths of a grain three times a day has been recommended in severe cases. A physician told me of one patient who took 100 of the 1/100 grain nitroglycerin tablets in one day with the effect of relieving a severe angina, and at that time he said the pain had not returned for three years. X usually took four or five of the tablets daily, and when the pain was worse or more persistent, ten or twelve. Frequently after these larger doses he would be entirely free from pain all the next day. From my personal observation, I think these large doses are often needed; and if the physician feels his way with gradually increasing doses, no harm will come from them unless they cause too much headache. Osler thinks nitroglycerin is too timidly used and is then abandoned as ineffective. The preparation should be reasonably fresh, and prescribed in the original package. It may be carried in a small closely stoppered bottle to prevent evaporation, and renewed from the original package every week or two. The patient should be warned of the possible dizziness, the flushing of the face and the headache resulting from its use, and should be assured that these disorders will do no harm. I have found it a good plan to give the patient 1/100 grain or more at once, so as to learn its effects before he leaves my office. After the susceptibility has been determined, it is best to give a full dose when attacks come on. It may be repeated as often as necessary to accomplish the result, except when it causes too much headache. The headache is sometimes relieved by repeating the dose. This remedy does no harm even from prolonged use. It is of doubtful utility when given only three times a day in the conventional dose of 1/100 grain.

X did not like amyl nitrite because of its odor, and also because during an attack he found it difficult to dispose of the glass. It is asserted that although this remedy acts quickly it is not as certain as nitroglycerin. The few times that X used it, its effects were practically nil.

Sodium nitrite disturbed his stomach, by the time two or three doses had been taken. This drug seems to have some toxic property. Erythrol tetranitrate caused more headache and did not relieve the pain as promptly as the nitroglycerin, although some patients have found it more satisfactory because of longer duration of its effects.

The heart may be protected against inhibition shock by more or less continuous use of atropin. The dose employed is often too small. As much as 2 mg. or 3/100 grain may be needed with some adults. In cases of extremely slow pulse, atropin has quickly relieved the inhibition. Calcium lactate is mentioned by some authors as a possible aid to check inhibition.

It is important to inquire into the cause; and if there has been syphilis, the proper treatment should be adopted, as potassium iodid and the arsenical preparations. Arsenic has been used since 1879, and is recommended in small or large doses to forestall the pain. The prolonged use of potassium iodid is said by some to be very effective. I myself have not seen much benefit from these remedies; but in view of the contention that nearly all cases of angina pectoris in persons less than 45 years old are syphilitic, it is possible that many of them might be benefited by these remedies.

During the attack, if prolonged and severe, morphin, or morphin and atropin, given together hypodermically, are the most common remedies. They are undoubtedly necessary in many cases, but they usually disturb the digestion and make the patient feel bad for two or three days, so that it is much better to give the nitrites first and rely on them when they will answer the purpose. Whisky in quantities of about 3 ounces will also give relief. Hot applications over the sternum, as an electric pad, are sometimes helpful in relieving pain. Balfour recommended chloroform to be inhaled from a wide-mouthed bottle in which about a dram had been placed on a sponge. The bottle was to be held in the patient's hand so that, as he came under the influence of the anesthetic, the bottle would drop and roll away. Allbutt considers chloroform dangerous. I do not know its value from personal experience in angina pectoris, but have found this method of administration very effective and safe in some other painful conditions.

On account of its reputed effect in contracting the arterioles, digitalis is not suited to relieve an acute attack. In those cases in which the heart's action remains practically normal, it is distinctly contraindicated. When the heart's action is feeble, however, this remedy and nux vomica are indicated. The two together will often yield results that cannot be obtained by either one given alone. X tried digitalis repeatedly, but became convinced that at times it made him worse, although he never had high blood pressure. In sixty cases I observed, in which the condition of the heart and pulse was recorded, the heart was apparently normal in thirty-six cases, and the pulse did not exceed 85 in twenty-six cases. In only eleven cases did the myocardium or valves appear to be involved, in only nineteen did the pulse run from 85 to 90, and in only twelve did it run higher than 90 at the time of my examination.

To prevent the attacks, it is of first importance that the patient live a regular life, and avoid over-exertion, mental excitement, chilling of the surface and, indeed, anything that brings on the pain.

Moderation in eating should be enjoined, especially on those who are overweight, and mild measures for reducing the obesity should be instituted. Tobacco, coffee and sometimes even tea should be avoided. Flatulence should be relieved by such remedies as rhubarb, gentian, and the carminatives, as peppermint, cardamom and ginger. The *Bacillus bulgaricus* has been quite effective in preventing flatulence in some persons. The secretions must be free and the bowels must be kept open.

Rest, especially in the early stages or when the attacks recur frequently, is of the utmost importance; but the patient's temperament must be considered, and the physician must not demand what to the patient seems impossible. I am impressed with the idea that rest and diversion with graduated exercise are the greatest factors in the beneficent effects of baths of the type given at Nauheim. Essentially the same baths may be given at home, by adding 9 pounds of sea salt and 10 ounces of commercial calcium chlorid to 40 gallons of water with or without carbonic acid gas. Calcium chlorid is probably the most essential ingredient. The carbonic acid gas appears to me negligible except for its psychic effect. As already pointed out, X improved markedly during his six weeks of treatment at Nauheim, and has continued to improve since. This case yields a hopeful aspect in prognosis and, I think, illustrates some important facts in treatment, the outstanding features of which are avoidance of exciting causes, heart tonics when needed, nitrites given freely to relieve pain, regular temperate habits, and abundant rest. I believe his improvement is due first to the free use of nitroglycerin, partly to the heart tonics he has taken almost continuously, partly to the care in diet, and largely to the hour and a half or two hours' rest every afternoon, added to the eight hours at night.

SUMMARY

The pain in angina pectoris is not usually in the heart and the left arm, but rather along the course of the aorta and larger arteries.

The pain appears, at least in many cases, to have no relation to the condition of the myocardium or to the obstruction of the coronary arteries.

A more hopeful prognosis than that of the usual conception of this disease may be assured under proper care and treatment, *a very important part of which is abundant rest with heart tonics as needed.*

The sublingual administration of fresh hypodermic tablets of nitroglycerin in large amounts to relieve pain is of great value. The failure of nitroglycerin is most often due to the wrong mode of administration, deterioration of the preparation, and inadequacy of the amount.

104 South Michigan Avenue.

PATHOLOGY OF ANGINA PECTORIS *

E. R. LeCOUNT, M.D.
CHICAGO

When sudden occlusion takes place in an artery supplying blood to a place which no other artery can adequately supply, because anastomosis with neighboring arteries is not sufficient, the process is called infarction and the name is generally applied also to the changes which result in the region having its blood supply so interfered with; the lesion produced is an infarct.

There are very few if any arteries which in a strict sense are terminal, that is to say, so terminal that the entire tissue supplied by them must of necessity die when their circulation is obstructed.

Many so-called terminal arteries are so in only a small degree, which means that only part of the region they supply undergoes death by anemic necrosis when they are abruptly occluded. Indeed, the existence of so many different degrees of terminality, if such an expression is allowable, has resulted in a great deal of contention between those who have maintained that arteries for some part of the human body were "end" vessels, and others who with equal vigor have insisted that they are not. Naturally these differences of view have led to experiments of one sort or another, to estimate in some precise way the extent to which the normal circulation in some of these terminal arteries is essential to the healthy life of the region supplied.

Unfortunately for many of these experiments, lower animals have been used; and the conditions for some organs at least, only approximate those in the corresponding human organ.

---

* Read before the Institute of Medicine of Chicago, March 28, 1918.

Exception may be taken also to the conclusions founded on conditions ascertained by anatomic studies, the injection of arteries supposed to be terminal to ascertain the extent such injection-masses may be made to penetrate the capillary bed and larger branches of neighboring arteries; for, valuable as these studies are, they do not measure the functional compensation possible by means of such anatomically demonstrable collateral anastomosis; in other words, proof by such methods of collateral communication is not a measure of the degree to which the vessels in question are functionally terminal.

The coronary arteries are virtually the sole route by which arterial blood is supplied to the heart. Because they possess some collateral circulation, and also of course because the maintenance of an adequate supply of blood by these arteries is necessary for life to continue, the amount of such collateral circulation in the human heart, and especially its ability to functionate in a compensatory way, has been subjected to extensive study.

Reference has been made thus far only to sudden occlusion; and it is worthy of comment at this time that experiments with the coronary arteries have practically all dealt with the consequences of obstructing the circulation in one or both of these vessels or their branches, by methods which have abruptly interfered with the circulation.

The relation impaired circulation in the coronary arteries is supposed to have to angina pectoris is, however, not limited to simply sudden or acute obstruction, but is believed to apply equally well to a gradual hindrance extending at times over many years.

It is generally believed that somewhere between sudden occlusion and its results, and such slowly developing obstruction that few or no symptoms develop, lie the lesions responsible for angina pectoris; and because of this I propose to discuss briefly such details as I possess regarding sixty deaths from difficulties with the circulation of blood in the coronary arteries or with lesions generally regarded as caused by such difficulty. These are in two groups: thirty-four deaths from fibrous myocarditis with sclerosis of the coronary arteries, and twenty-six of more or less acute occlusion.

FIBROUS MYOCARDITIS

Only four of thirty-four persons whose deaths from the postmortem examination were found to be due to fibrous myocarditis were in a hospital for any time and ill from heart disease; one for eight hours, with a clinical diagnosis of acute dilatation of the heart; one for 8.50 hours, with a diagnosis of pulmonary tuberculosis; a third, 17.40 hours, with a diagnosis of asthma, and the fourth for 27.50 hours, with a diagnosis of delirium tremens.

Twenty-eight of these thirty-four patients were men and six were women. Three under treatment for other illness and convalescent died suddenly and unexpectedly, eight died en route to the hospital, and eighteen were found dead; and of these last, four fell dead on the street and seven were found dead in bed.

In five of the thirty-four hearts the scars were of such size in the heart muscle that pouching outward had taken place—the so-called chronic parietal aneurysms. In a few the scars replaced so little of the myocardium that, in addition to other examinations, a chemical examination was made for poisons. In four of the thirty-four bodies, gross indications of syphilis were present, in four others there was pulmonary emphysema of the hypertrophic variety, in two the kidneys were markedly diseased—"small red granular kidneys." There was some anasarca or hydrops or both in eight of the thirty-four, obesity in one, and two hearts possessed anomalies, a two-cusped aortic outlet in one and absence of a circumflex branch of the right coronary artery in the other, the corresponding branch of the left coronary being large.

Four of the thirty-four patients were between 30 and 40 years old, eight between 40 and 50, thirteen between 50 and 60, six between 60 and 70, and one over 80 years. It will be noted that the decade for the greatest number was between 50 and 60.

One man, a pedler, aged about 60, came into a saloon and said he wished to rest, and later was found dead in the back room on a couch where he had lain down. The man in the hospital for 8.50 hours said he had been ill for three days, unable to retain anything on his stomach, but also unable to attribute this to any indiscretion in diet. Another was under treatment in the hospital for urethral stricture, went to the toilet, and on returning dropped dead at the bedside.

Another found sick on the street by a policeman died soon after being taken into a barber shop. Another dropped dead shoveling sand; one died suddenly in a police cell; one of the six women dropped dead when prepared to leave her work in the Psychopathic Hospital, where she worked nights; she had just dressed to leave. Another woman fell dead on the street, and a third woman died suddenly in a drugstore.

ACUTE CORONARY OBSTRUCTION

Of twenty-six persons who died with acute or suddenly developing obstruction of the coronary arteries, eighteen were men and eight women. Of these the age of the greatest number in any single period of ten years is two decades earlier than those with the fibrous myocarditis, one being in the 20 to 30 decade, eight between 30 and 40, six between 40 and 50, six also between 50 and 60, three between 60 and 70, and two 71 years old or over. This earlier age for the largest number in any one decade is no doubt connected with syphilis, for in eleven of the twenty-six bodies, changes usually regarded as indicative of syphilis were found, whereas with the thirty-four deaths from fibrous myocarditis, only four were of persons whose bodies possessed such alterations. Of the twenty-six patients, five died in the examining room, five were found dead, and one died en route to the hospital.

The obstruction of the coronary circulation of these twenty-six persons was in most instances thrombosis; in one instance embolism was associated with thrombo-ulcerative mitral endocarditis, and embolic hemorrhages were present in the skin and bowel as well. In another heart acute dissection of the wall of the circumflex branch of the left coronary artery was associated with a minute sacculated aneurysm at the same place. In a third the coronary artery broke open and the blood from it found at the postmortem examination in the pericardial sac weighed 560 gm. In four others, syphilis of the root of the aorta had obstructed the coronary circulation at the mouths of the arteries. One of these was interesting in that a small globular clot formed where the intima of the aortic root was altered from syphilis, had obstructed the mouth of the left coronary artery completely. Another concerned a pregnant housewife only 21 years of age.

In another heart the obstruction was apparently due to calcareous masses which were partly loosened in the channel by softening of patches of atheroma of which they were a part. This man, aged 60, had become acutely ill, and was on his way to the hospital without aid. He had almost arrived when overcome. He died in the examining room. In addition to the obstruction with loose lime masses and the infarction of the myocardium, the anterior papillary muscle was found greatly atrophied and shrunken, there was some fibrous myocarditis, and the heart weighed 455 gm.

Mention has been made of a small saccular aneurysm of the branch of the left coronary artery, which runs around the heart referred to here as the circumflex branch, and its association with acute dissection of the artery wall at the same site. In two other hearts the obstruction was similarly located, once in the left circumflex branch and once in the right.

The regions of infarction in these hearts were for the most part large and easily found; many were, as is commonly known to be the case, considerable distances away from the place where the artery was occluded or the circulation otherwise interfered with. Infarcts of the myocardium are frequently multiple, and sometimes small and widely scattered.

In one of these twenty-six hearts the place softened by anemic necrosis broke so that the pericardial sac filled with blood; in several, acute outpouching in varying degrees was present; in many, mural thrombi had formed on the necrotic lining. Small, delicate deposits of fibrin on or in the epicardium of the place infarcted was not uncommon.

These twenty-six deaths from more or less acute obstruction of the coronary circulation are the only ones of 175 deaths from heart disease with which I have found associated symptoms suggestive of angina pectoris.[1] Fifteen of the twenty-six were patients for a short time. The shortest period under observation was 1.15 hours, and the longest, 52.20 hours.

The diagnoses made in these short periods are of interest. Twice the diagnosis of angina pectoris was made; for two others, acute dilatation of the heart; for one, edema of the lungs; for two, lobar pneumonia; and once each, pulmonary tuberculosis, acute gastritis, intestinal obstruction and carcinoma of the stomach.

One of these acute coronary obstructions had to do with the heart of a man found dead seated in a chair. He had been ill two months and under the care of a surgeon well known to us all whose diagnosis of gallstones I have in a letter in answer to one of inquiry sent him. I found no gallstones, and there had been no operation. The following are brief synopses of single cases:

Time under observation, 26.10 hours. An elevator man, aged 61. Illness began five days before entrance with a sudden pain in the chest which spread to each side and was increased by deep inspiration. There was vomiting at intervals during these five days.

Time under observation, 16.20 hours. Age, 30; Italian. Three days before death there was pain in the lower chest and abdomen with vomiting. The respirations were from 32 to 40. The pulse was too fast to count. The clinical diagnosis was lobar pneumonia.

Time under observation, 52.20 hours. A German woman, aged 43, a nurse. Illness began two and a half days before death with pain of the back of the neck, front of the neck and across the chest pronounced neuralgia by one physician, and heart disease by another. In the hospital the pain was all on the left side and involved the neck, both extremities and the left side of the chest. The clinical diagnosis was angina pectoris.

Time under observation, 28.15 hours. Woman, aged 50, housewife. Illness began five days before with vomiting one and a half hours after eating a heavy meal, and severe cramplike pains of the epigastrium persisting during the five days.

Time under observation, 8.30 hours. Man, aged 35, became ill twenty-two days before death after working fourteen hours without food in a brickyard, with pain in the chest and shortness of breath, and vomiting for several days shortly after eating. When in the hospital he did not have much pain, but spat up a blood-stained froth and was very cyanotic. The clinical diagnosis was edema of the lungs.

Time in the hospital, 20.15 hours. Man, aged 53, telegraph operator. While walking two weeks before death his illness began suddenly with a severe pain in the chest, and he was obliged to stand still or lean against something for support and gasp for breath. This lasted only a few minutes, but was repeated three or four times in walking a block. Four days before coming to the hospital he had a similar attack in bed, and a physician came and gave him a hypodermic and he had suffered but little pain since; but the shortness of breath persisted and remained worse on slight exertion during all the two weeks. The clinical diagnosis was angina pectoris.

COMMENT

It may be assumed that none of these sixty persons suffered from angina pectoris, that there are no reliable accounts of the angor said to be associated with a sense of impending death or that many were examples of pseudo or mock angina. I have no answer to such assertions unless it be to state that in all likelihood many die from true angina in a first attack and that some people with true angina suffer as others do but without any realization that death is at hand; no doubt people vary as to their ability to discriminate with regard to the likelihood of death ending their distress and with regard to their fear of death.

As to the contention by Allbutt that the lesions are not located in the coronary arteries but in either functional or structural alterations of the aorta, I may remind you that anatomists have always debated somewhat as to where the heart ends and the aorta begins, where the boundary line between them lies.

Since the lower part of the aorta as well as of the pulmonary artery receives its blood supply from small branches of the coronary arteries, which, passing up, anastomose with similar vasa vasorum from the bronchial and pericardial arteries, it perhaps may be best to regard the proximal few centimeters of both of these large arterial trunks as a portion of the heart.

It is not unlikely that with sclerosis of the coronary arteries a difficulty exists in maintaining an adequate supply of arterial blood to the proximal parts of these arteries, a difficulty which is concerned with insufficient anastomosis with the other vasa vasorum which come down from the bronchial and pericardial arteries; indeed, these last vessels may also be the seat of sclerosis.

With these conditions in mind, it is easy to conceive of these branches of the coronary arteries which supply arterial blood to the roots of the pulmonary artery and aorta as end arteries in much the same way as their chief branches to the myocardium are terminal, and to remember that, although a collateral anastomosis exists in the heart between the two coronary arteries and also between the coronary vasa vasorum of the aorta and other vasa vasorum to the aorta from the pericardial and bronchial arteries, with sclerosis or with more acutely developing obstruction from other causes, the compensatory circulation may prove inadequate or may not be promptly enough established to prevent either angina pectoris with death, or death so unexpectedly that there is no opportunity to determine whether symptoms of angina did or did not occur.

---

[1] These 175 necropsies were all medico-legal, a part of inquiries necessary because the deaths were unexpected, or because of an absence of medical attention sufficient to ascertain the nature of the illness.

[Note.—This and the paper by Dr. Ingals which precedes it are part of a symposium on angina pectoris read before the Institute of Medicine of Chicago. Abstracts of the remaining papers appear in the society proceedings in this issue of The Journal.—Ed.]

ARE DIPHTHEROIDS A FACTOR IN FEMALE STERILITY?

T. C. STELLWAGEN, Jr., M.D.
Assistant Professor of Genito-Urinary Surgery, Jefferson Medical College
AND
P. S. PELOUZE, M.D.
Assistant Genito-Urinary Surgeon, Genito-Urinary Dispensary, University of Pennsylvania Hospital
PHILADELPHIA

The problem of sterility is of great importance to the human race. This is especially true at the present time when the flower of manhood and womanhood is being destroyed or maimed by war. We believe that the question of sterility does not receive sufficient study from investigators. With the dawn of peace will come the problem of the rehabilitation of mankind, and we feel that any procedure that offers assistance to humanity should be discussed. On matters of such magnitude as generation, we believe we shall be pardoned if we submit a single rather striking case for consideration. We aim to place before the profession a clinicolaboratory experience, hoping thereby to induce investigators of greater ability to study along this line. Valuable work has been done on the bacterial flora of the female genitalia. Little, if any, appears to have been done to ascertain the possible effects of such flora on procreation.

It is with the foregoing ideas that we report this case, presenting apparently important phases.

In the fall of 1916, Dr. X, a dentist, presented himself for study as to the cause of an anterior urethral discharge. In the history he stated that he had been married seven years, during which period he had never had any urethral discharge, nor had there been any extramarital exposure.

A study of his discharge showed it to be very largely composed of pus cells and epithelial elements. The only bacterium present was of the Hoffmann type of the pseudodiphtheria bacillus. This was obtained in pure culture from the anterior discharge and also from the prostatic secretion. He was given the usual routine local treatment for such conditions. He improved and the anterior discharge became scanty and at times disappeared. The prostatic secretion, however, still presented numerous leukocytes and organisms. The condition of the prostatic secretion and its tendency to remain in statu quo led us to reinforce our local treatment by an autogenous vaccine. Under the added impulse of vaccine therapy, the prostatic secretion became normal. At the time of making the vaccine, we deemed it wise to study the bacterial flora of the wife's genital tract with a view to determining the source of his infection and thereby obviating the possibility of future attacks. This study particularly appealed to us because of the fact that, some time previous, she had been under the care of an eminent gynecologist for a year and a half, for the purpose of correcting an apparent sterility. During this period, she had been given intravaginal medication, dilatation and curettage, and had undergone an abdominal operation for the correction of a malposed uterus. These procedures, however, failed to bring about conception, though the husband's seminal fluid contained countless numbers of very motile spermatozoa.

Our study showed that there was a complete absence of vaginal discharge. Cultures were taken from the wife's genital tract. Those from the vaginal vault presented the usual flora, with a preponderance of diphtheroids.

The cultures from the cervical canal proved to be purely diphtheroids. From a five-day growth of these bacilli, it was possible to demonstrate almost all the Westbrook types of the diphtheria bacillus, with many striking metachromatic forms. Separate autogenous vaccines were made and used on the husband and wife. Both patients canvalesced promptly with a virtual disappearance of the diphtheroids.

About three months after their dismissal, the husband returned for examination and was found free from his former infection. He was gratified to relate that he thought his wife was two months pregnant and wished us to refer him to an obstetrician for confirmation of the surmise. This was done and a positive report returned. Nov. 20, 1917, she gave birth to a healthy girl baby.

We have since had an opportunity to study bacteriologically two cases of female sterility. In one of them a pure culture of diphtheroids was obtained from the cervical canal. In the other, studied for Dr. Alexander Randall, there was a mixed culture in which diphtheroids predominated. These patients are now under treatment with autogenous vaccines in distant cities, but it is as yet too early to make a further report on their progress. We know that we have proved nothing by our meager experience, but we feel that it may encourage further study.

THE FORMATION AND COMPOSITION OF THE CEREBROSPINAL FLUID

A SIMPLE METHOD OF DETECTING ACIDOSIS AND DETERMINING HYDROGEN ION CONCENTRATION *

J. F. McCLENDON, Ph.D.
MINNEAPOLIS

THE CEREBROSPINAL FLUID

The view has been repeatedly expressed that the spinal fluid is a secretion and its composition more or less independent of the composition of the blood, but the experiments described in this paper do not favor this view. The spinal fluid is not an ordinary filtrate, such as lymph, since it is almost free from proteins, in health. It may be, however, an ultrafiltrate. Bechhold impregnated filters with colloids so that they became impermeable to proteins, and he called the apparatus an ultrafilter since it filtered out ultramicroscopic colloid particles. It seemed advisable to compare the ultrafiltrate of blood plasma with spinal fluid. The apparatus was prepared as follows: An alundum extraction shell of the finest grade was heated in a blast lamp to remove all organic matter and washed in distilled water several days to remove soluble substances. It was dried, and a perforated rubber stopper was inserted in the open end. The shell and part of the rubber stopper were coated with a solution of collodion and rotated until the smell of ether was faint, and then placed in distilled water until needed. The ultrafilter thus formed was drained and immersed

---

* From the Physiological Laboratory of the University of Minnesota Medical School.

in dog's oxalated plasma, and the perforation in the rubber stopper was connected with a suction pump and a pressure of about 380 mm. was applied. After a few cubic centimeters of filtrate had collected inside the filter, it was removed through the perforation in the stopper and the filtration continued.

The plasma had been diluted with potassium oxalate solution, and its alkaline reserve was 0.018 normal as determined by titration in the rotating hydrogen electrode.[1] The alkaline reserve of the ultrafiltrate was 0.016 normal by the same method, or roughly 10 per cent. less. The alkaline reserve of the spinal fluid was found to be about 10 per cent. less than that of undiluted plasma. The possible explanation of this difference is that 10 per cent. of the alkaline reserve of plasma is in the form of sodium albuminate, which will not pass the filter, and 90 per cent. in the form of sodium bicarbonate, which passes freely.

The freezing point of the plasma was — 0.66 C., and of the filtrate — 0.62 C., or a difference of 0.04 degree, which corresponds to a difference in osmotic pressure of 380 mm., which was the difference in pressure on the two sides of the filter membrane. If the spinal fluid is an ultrafiltrate, the difference in pressure on the two sides of the filter membrane is the difference between the capillary blood pressure and the pressure of the spinal fluid, and is very small. In support of this supposition is the fact that the difference between the freezing points of human blood and spinal fluid is very small. The freezing point of human blood is usually — 0.56 C., but may vary from — 0.48 to — 0.62. I found the freezing point of one sample of human spinal fluid to be — 0.56, and Mott found variations from — 0.51 to — 0.56. If the spinal fluid is an ultrafiltrate of blood plasma, the concentration of sugar, urea and diffusible salts should be the same in each at the place of formation; but *subsequently*, sugar might be decreased and urea increased in the spinal fluid, as a result of metabolism of nerve tissue. This condition seems to exist, as shown by Table 1, which also shows that the dissolved gases are similar *in concentration.*

TABLE 1.—COMPARISON OF THE CONTENT OF THE SPINAL FLUID AND THE PLASMA

Substance	Parts per Thousand in Spinal Fluid	Blood Plasma
Glucose	1.3 to 2 (Mott)	0.6 to 2
Urea	About 0.4	About 0.4
Total inorganic salts.	8.78 (Halliburton)	8.574 (Carl Schmidt)
Sodium chlorid	7 (Harding and Mason)	6 (Harding and Mason)
Potassium chlorid ...	0.28 (Halliburton)	....
Diffusible calcium ...	0.05 (Halverson and Bergeim)	0.07 (Rona)
(Alkaline reserve) ..	(0.0275 normal)	(0.03 normal)
Calculate sodium bicarbonate	2.3	2.3
Total carbon dioxid..	About 600 (Mott)	About 600
(Oxygen tension) ...	(27 to 115 mm. calc. from Mott)	(40 to 115 mm.)

It seems probable, therefore, that the spinal fluid is formed primarily by ultrafiltration, and that to this filtrate the secretions of cells may be added. The high protein content in disease may be explained by the supposition that the disease causes leakage of the filter, thus allowing protein, and sometimes cells, to pass through. The pressure of the spinal fluid might indicate whether or not the leakage came partly from the arterioles.

If the spinal fluid is an ultrafiltrate of the blood, o is in diffusible relation with it, any change in the alka line reserve of the blood plasma should cause a chang in the same direction, in the spinal fluid. To test thi two normal dogs were etherized and into one of the hydrochloric acid was injected intravenously unt death occurred. *The skulls of the dogs were opene* and spinal fluid taken from *the region of the fourt* ventricle. The alkaline reserve of the spinal fluid (*the normal dog was 0.0225* normal and that of the do in experimental acidosis, 0.02 normal. Since a lowe ing of the alkaline reserve of the blood plasma lowe that of the spinal fluid, how much more easily must lower that of the lymph and the tissue fluids. Th alkaline reserve of the cells of the body may be low ered also. The injected dog weighed about 26 k Let us assume that the volume of the dog was 25 liter It was injected with 500 c.c. of tenth-normal hydr chloric acid (in physiologic sodium chlorid solution and 250 c.c. of 0.2 normal hydrochloric acid (in th same solvent), or the equivalent of one liter tenth normal hydrochloric acid. This should have lowere the alkaline reserve of its body 0.004 normal. Th alkaline reserve of the spinal fluid was lowered 0.002 normal, but if the dog had lived until a more perfec equilibrium was established between blood and spina fluid, the lowering of the alkaline reserve in the latte would probably have been much greater. The dog died about one hour after the injection was begun.

TABLE 2.—CHANGES IN ALKALINE RESERVE OF SPIN FLUID OF DOGS

Method Used to Quiet Dog	Alkaline Reserve o Spinal Fluid
Morphin	0.026
Curare	0.022
Death by bleeding	0.023

It has been stated by Henderson and Cannon that the alkaline reserve of the blood plasma is changed by drugs and by shock, and Cavazzani found similar changes in the alkaline reserve of spinal fluid of dogs as set forth in Table 2.

He found the alkaline reserve of spinal fluid of rabbits to be from 0.021 to 0.025, and of an ox, 0.026.

TABLE 3.—DETERMINATIONS OF ALKALINE RESERVES IN THE SPINAL FLUID OF PATIENTS

Case No.	Alkaline Reserve	Diagnosis
1	0.015	Diabetes
2	0.023	Tabes dorsalis
3	0.025	Sciatica
4	0.026	Myasthenia gravis
5	0.026	Cerebrospinal syphilis
6	0.027	Hysteria
7	0.027	Syphilis (Wassermann negative on spinal fluid)
8	0.027	Nephritis
9	0.027	Neurosis
10	0.027	Neurasthenia
11	0.0275	Nephritis
12	0.0275	Tabes dorsalis
12	0.0275	Tabes dorsalis
2	0.0275	Tabes dorsalis
13	0.0275	Mitral stenosis
14	0.028	Epilepsy
15	0.030	Diabetes

Mott found that the alkaline reserve of human spinal fluid was usually 0.0275.

My determinations of the alkaline reserve of the spinal fluid of patients in the University Hospital are shown in Table 3. It may be noted that nearly all cases show that the alkaline reserve is 0.027 or 0.0275 without reference to disease. The few cases of diabetes do not admit of certain conclusions except that the alkaline reserve was very variable. This was also shown in alveolar carbon dioxid and blood plasma combined carbon dioxid.

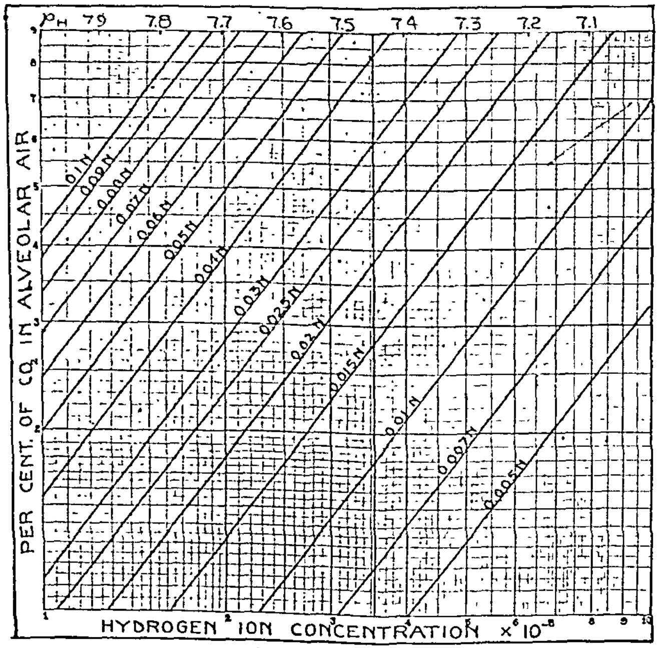
---

[1] McClendon, J. F.: Jour. Biol. Chem., 1917, 30, 265.

METHOD OF TITRATION OF CEREBROSPINAL FLUID, AND OTHER METHODS FOR DETECTION OF ACIDOSIS

Since a lowering of the alkaline reserve of the blood causes a lowering of that of the spinal fluid, any dangerous degree of acidosis, that is, the lowering of the alkaline reserve of the whole body, should cause a noticeable change in the spinal fluid. Cavazzani and Mott titrated the spinal fluid and at least their later titrations were probably done properly, but they do not make it clear that errors due to proteins or to carbon dioxid were avoided.

I developed an electrometric method for titrating the alkaline reserve of blood plasma.[2] In applying this method to the spinal fluid, I found that the proteins are so low in concentration that it is possible to titrate the fluid with a suitable indicator. The indicator chosen must show a sharp color change at a reaction just on the acid side of the neutral point, in order to be sensitive and avoid any errors due to carbon dioxid, and must be relatively little affected by proteins and other substances. It is, however, impossible to find an indicator that is not rendered worthless by as large an amount of protein as occurs in the blood plasma. It was found that dibromorthocresolsulphonephthalein is admirable in the titration of spinal fluid into which no hemorrhage has taken place, whereas it is worthless in the titration of blood plasma. The method is as follows:



Conversion table.

One c.c. of spinal fluid is carefully measured in a volumetric pipet and run into a porcelain dish. Enough of an alcoholic solution of the indicator is added to turn it a distinct purple. The buret is improvised out of a 1 c.c. pipet, graduated in hundredths of a cubic centimeter. To the lower end of the pipet is attached a short piece of rubber tubing of 1 mm. bore. Into the lower end of the rubber tubing a piece of small glass tubing is inserted. The glass tubing is drawn out in a flame to a capillary tip. The rubber tubing is closed by means of a small clip, of the type of crossed forceps or the bull dog or the Langenbeck clip. When the titration is made the buret is filled with tenth-normal hydrochloric acid. The acid is run in, a small portion at a time, and is mixed with the spinal fluid by being shaken in the porcelain dish until the color changes to yellow. It will be noted that the purple color may return on further agitation and that the end-point is reached only when the purple fails to return. In order to reach the end-point exactly, I find it necessary to split drops. That is to say, the drops that fall by gravity are too large; and when a very small drop of hydrochloric acid is allowed to form on the tip of the glass tubing, it is transferred by touching the porcelain dish a short distance above the surface of the spinal fluid, and then is thoroughly mixed by agitation of the dish.

The results are put down as in the ordinary titration of an alkali with tenth-normal hydrochloric acid; for instance, ordinarily 1 c.c. of spinal fluid requires 0.275 c.c. of tenth-normal hydrochloric acid. In other words, the spinal fluid is 0.0275 normal in "alkalinity" or, as is more properly stated, in "alkaline reserve." This alkali exists almost entirely in the form of sodium bicarbonate, and therefore during the titration, the fluid must be agitated until the carbon dioxid is expelled before the titration is complete. It is unnecessary, however, to boil in order to expel carbon dioxid.

There are several methods of determining the alkaline reserve of body fluids containing protein. The titration method[2] gives results in the same terms as those given in the foregoing. The method of Van Slyke gives the results in terms of combined carbon dioxid. In order to reduce these results to normality (N) of bicarbonate, it is only necessary to know that the carbon dioxid combined in 1 c.c. of a normal (1 N) solution of sodium bicarbonate occupies 22.4 c.c. at standard temperature and pressure. When the Van Slyke apparatus is used, however, it is possible to determine either the combined or the total carbon dioxid in the blood plasma or other fluid. These differ slightly from one another (by about 4 c.c.). Table 4 may be used to give the results obtained by the different methods in terms of one another. In the first column are given the results by the titration method, in the second column, the so-called combined carbon dioxid, and in the third column, the total carbon dioxid after saturation at 42 mm. partial pressure and 20 C.

Table 4 is supposed to be correct within 10 per cent. As stated in the foregoing, the sodium bicarbonate of plasma and the spinal fluid seem to be the same, but the plasma seems to have 10 per cent. more reserve in the form of sodium albuminate. This would cause the carbon dioxid of the plasma to be 10 per cent. less than that of spinal fluid of the same alkaline reserve, but this seems not to be the case. I have found the alkaline reserve of plasma to be about 0.03 normal (corresponding to 67 c.c. of combined carbon dioxid), and Van Slyke states that the combined carbon dioxid of plasma is 65 per cent. instead of 61 per cent., as would be expected. It seems possible that about 3 per cent. of the carbon dioxid [illegible]ly comb[illegible] with colloids of the plasma by adsorption or loose chemical union. Because of technical errors in the methods, separate tables for spinal fluid and plasma are hardly worth while.

---

[2] McClendon, J. F.: Jour. Biol. Chem., 1918, 33, 19.

HYDROGEN ION CONCENTRATION

Owing to the frequency of technical errors in taking samples or determining hydrogen ion concentration of blood or spinal fluid, the results very seldom have anything like the accuracy that is possible if unlimited time is taken to achieve the greatest accuracy. I have found that the use of the conversion table shown in the accompanying chart gives much more reliable results than those usually obtained by any direct method. The table is not absolutely correct. If it were correct in one part for blood plasma, it would not be absolutely correct for spinal fluid; but the difference would be less than the error, often vitiating direct determinations.

The method is based on the assumption that the hydrogen ion concentration of blood and spinal fluid is the same as that of a solution of sodium chlorid and sodium bicarbonate of the same osmotic pressure, alkaline reserve and carbon dioxid tension as the blood or the spinal fluid. The peculiar form of the conversion table was arrived at empirically after a prolonged study of bicarbonate solutions,[1] and was adapted empirically to blood plasma.[3] The fact that it holds for spinal fluid within 10 per cent. error in alkaline reserve and technical errors in the hydrogen ion determination follows for the reason that the alkaline reserve, carbon dioxid tension, and hydrogen ion concentration of blood plasma and spinal fluid in the same person are practically the same; or more definitely, the alkaline reserve differs by about 10 per cent. The carbon dioxid tension is about the same, since the alkaline reserve is about the same and the total carbon dioxid about the same. The hydrogen ion concentration can be calculated from the p_H (— log hydrogen ion concentration) and since the p_H is about the same for spinal fluid and blood, the hydrogen ion concentration is about the same. The p_H of blood is about 7.45. Felton, Hussey and Bayne-Jones,[4] using the colorimetric method, found the p_H of spinal fluid to vary between 7.4 and 7.6. If this method is used with spinal fluid, 0.1 should be subtracted from the reading on account of salt error, and a further subtraction would be desirable on account of protein error, and loss of carbon dioxid from the spinal fluid. The error in reading the color may be nearly 0.1, and the error in making the standard, greater than 0.1. It seen evident that the difference in the reports of the p_H blood and spinal fluid is within the limits of err where no corrections have been applied.

TABLE 4.—ALKALINE RESERVE (BICARBONATE)

Titration Normal	Volume Per Cent. Total Carbon Dioxid	Volume Per Cent. Combined Carbon Dioxid
0.010	27	22
0.012	31	27
0.014	35	31
0.016	40	36
0.018	45	40
0.020	49	45
0.022	53	49
0.024	58	54
0:026	62	58
0.028	67	63
0.030	71	67
0.032	76	72
0.034	80	76
0.036	84	81
0.038	89	85
0.040	93	90

In using the conversion table shown in the chart, is assumed that the carbon dioxid tension of the blo and the spinal fluid is the same as that of the alveol air as determined by any method that may be chose The alkaline reserve is determined by titrating t spinal fluid and the diagonal of this alkaline reser found in the chart. The alveolar carbon dioxid measured on the ordinate with a pair of divide which are moved to the right until their upper poi falls on the alkaline reserve diagonal. At their low point, the hydrogen ion concentration of spinal flu (and blood) may be read off. The p_H may be foun by following the vertical line from the hydrogen i concentration to the top of the page.[5]

A CASE OF TIN POISONING*

MOSES SALZER, M.D.

CINCINNATI

Jan. 29, 1917, H. M., a traveling salesman, aged 59, co sulted me on account of a feeling of coldness or chilline and sore throat. He said that he had felt chilly for a wee or more. His temperature was 102.5, and his throat was re His tongue was very much coated. He had a full uppe and lower set of false teeth. The physical examination wa otherwise negative. I sent him home and told him to g to bed. The following day I called on him. His temperatur was still over 102, and both tonsils were covered with whit spots. A diagnosis of acute tonsillitis was made at thi time. In four days his temperature was normal, his throa had cleared up, and I discharged him as cured.

February 21, or three weeks later, he again consulted me saying that he was not a bit better and that he had had t discontinue his business trip because he felt bad. He stil felt chilly. This chilly feeling would be relieved occasionall by hot flashes. On arising in the morning, he said that h felt as if he were stepping into a tub of ice-water. Hi throat also continued to annoy him. He had indefinite, vague pains in his extremities and the back of his head. The examination of his throat was negative. He said that this feeling of coldness was so persistent and annoying that he was unable to eat, sleep or attend to his business. His tongue was still heavily coated. His blood showed 3,500,000 reds, 6,200 whites, and 70 per cent. hemoglobin, but there were no morphologic changes. Repeated examination failed to reveal anything outside of this slight anemia. The Wassermann and Hecht-Weinberg tests were negative.

March 3, Dr. Roger S. Morris saw him in consultation, and was unable to throw any further light on the case. We both agreed that the condition was one of simple anemia following the attack of fever and sore throat in January, and advised that he go to Old Point Comfort for a rest. He did not go, but continued to consult me daily or oftener. His chief complaints were the feeling of coldness and the soreness in his throat. Drs. Iglauer and Allen both examined his throat, and their findings were negative. His temperature was always normal.

March 22, he returned with the same complaints, coldness, irritation or pain in his throat, and indefinite pains in his legs, arms and head. I examined his throat again but found nothing. I told him, however, that I would touch his throat up with some silver nitrate. He then took out his lower set of teeth and, seeing that they attracted my attention, he said that the teeth were set in tin. This statement was confirmed by his dentist, who stated that the plate was made of Watt's metal, which is two-thirds tin and one-third bismuth. Immediately the possibility that the case was one of tin poisoning flashed through my mind, although I had never heard of such a case. I reasoned, however, that if other heavy metals could produce poisoning, possibly tin also could do so. The patient had been wearing this lower set since Dec. 11, 1916, or about one month before the symptoms began. I told him not to wear the lower set of teeth, which showed evidence of corrosion in spots, until I had had an opportunity of looking up the literature on the subject.

* Read before the Academy of Medicine, Cincinnati, Feb. 25, 1918.

The literature abounds in references to so-called tin poisoning in which tinned foods were partaken of. The symptoms in these cases were confined to the gastro-intestinal tract and were those of an acute poisoning. I was able to find references to only two cases in which tin had been absorbed and had given rise to constitutional disturbances, and one of these was reported by Jolles[1] in 1901. His patient showed constitutional disturbances due to wearing silk stockings impregnated with tin salts. In this case the predominating, outstanding symptom was this feeling of coldness which my patient complained of. Jolles proved that his was a true case of tin poisoning by finding tin in the urine of his patient.

In my own patient the urine passed on the day following he discontinuance of the wearing of the plate contained races of tin. No other specimens of the urine showed any races. The patient was placed on a diet free from canned oods, and a few days later the stool was examined. Approximately 5 gm. of dried stool contained 0.0021 gm. of metallic in. Several subsequent examinations of the stool showed he presence of tin.

April 6, 1917, or fifteen days after the patient had discontinued wearing the plate, 13 c.c. of the blood contained).0015 gm. of tin. No other foreign metals were found in the blood. The patient still complained of the same symptoms, although they had ameliorated somewhat. The coating from his tongue had almost disappeared. Considering the marked affinity of tin for proteins, it is not remarkable that the symptoms continued. I prescribed potassium iodid then, and on the 13th of April, or one week later, 20 c.c. of his blood contained only 0.0005 gm. of tin, showing that more than two thirds of the tin had been eliminated during the week. No subsequent examination of the blood, urine or feces showed any traces of tin. The anemia gradually cleared up.

The chemical analyses in this case were made by Mr. F. C. Broeman, consulting chemist, and also by Mr. Clarence Bahlman of the Cincinnati Department of Health. They made their tests independently, using parts of the same specimens, with identical results.

Considerable experimental work has been done with regard to the effects of tin salts when administered to animals. Salant, Rieger and Trenthardt[2] showed that after subcutaneous injections of soluble tin salts, tin was found in the urine, feces, skin and liver. The gastro-intestinal tract was shown to be the chief organ for the elimination of tin.

Ungar and Bodlander[3] and Lehman[4] showed that repeated injections of small quantities of tin into animals, over prolonged periods, resulted in the death of the animals. The effects were manifested in the alimentary tract, the general nutrition and, above all, in the central nervous system. Paralyses of the extremities were frequently observed.

In an experiment conducted by Schryver,[5] a dog, weighing 8.5 kg., was given 20 mg. of tin subcutaneously in the course of several days, and the animal was then killed. The brain and cord of this animal weighed 65 gm. Twenty gm. were submitted to examination and contained 1.5 mg. of tin.

It is apparent from the foregoing that tin must have a rather strong affinity for nervous tissue.

I lost sight of the patient, and did not see him again until Sept. 14, 1917. He came to me complaining of the same symptoms, but in a milder form. He said that he had been under the care of Dr. Marion Whitacre, by whom he had been sent to Dr. Mithoefer who, July 12, 1917, removed his tonsils and reported both badly diseased. I saw the patient again, October 17 and November 1, and he was still complaining of the same symptoms. He was, however, attending to his business and his appetite was normal.

This patient has since passed from under my care, and the last I heard of him he was making the "rounds" from one physician to the other still complaining of his "hots and colds," although he is now able to attend to business.

The onset of the symptoms within a few weeks of the patient's starting to wear the Watt's metal plate, and the finding of the tin repeatedly in the blood, stool and urine by two chemists working independently of each other, and then the disappearance of the tin from the blood after the patient discontinued the wearing of the plate are to my mind incontrovertible evidence in support of my diagnosis. His symptoms were almost identical with those of Jolles' patient.

In view of the experiments quoted above, in which so much tin was found in the nervous system, I feel reasonably certain that this man's nervous system suffered severely, and possibly permanently, which accounts for the persistence of his symptoms.

SURGICAL TREATMENT OF EPIDIDYMITIS *

RICHARD L. COOK, M.D. (WASHINGTON, D. C.)
Major, M. R. C., U. S. Army
FORT SAM HOUSTON, SAN ANTONIO, TEXAS

The question of venereal disease in the Army since the outbreak of the present war has been an all absorbing one. Special attention has been paid to cleaning up the various training centers, and this has accomplished a great deal; but we still have the acute gonorrheal infection with its complications.

In this brief paper, I am going to deal only with the acute and subacute gonorrheal epididymitis. I have had the opportunity of observing and operating on 276 patients since entering on my duties at Fort Sam Houston as chief of the genito-urinary service.

There are many advocates of the nonoperative treatment, which utilizes only palliative measures and in no way cures the condition. It is advanced that men can be returned to duty sooner; but I do not agree with this, as I have returned them to duty as soon as the stitches were removed. The average time in the hospital on account of the operation has been less than ten days. There is often some induration which remains for a longer period, but it does not incapacitate. I have had no recurrences, but have had a number of soldiers, suffering great pain, report for a second operation several weeks later, this time on the other testicle. This goes to show that the almost immediate relief from pain following the operation makes the procedure justifiable. Not only does it relieve the pain, but also there is, as a rule, a beginning hydrocele, which is cured at the same time. There has been no proof obtainable, but the conclusion is drawn that an epididymis operated on, with evacuation of pus, which occurred in 33 per cent. of the cases is much more apt to function than one allowed to resolve partially through applications of ice and support. Those subacute cases in which operation has been performed are always indurated, and the tail of the epididymis is much enlarged. Of course, the question of preventing any loss of function in these cases is questionable, the pus is often found and the destruction is certainly diminished. The patients give a history of numerous attacks, with pain and swelling, which are relieved by palliative measures.

* F [illegible] pital No. 1, Fort Sam Houston, Texas.

The breaking up of the adhesions to the parietal layer of the tunica vaginalis is most essential. This is best done with the finger and a piece of gauze. Any lymph collecting between the layers of the tunica vaginalis should be removed with gauze.

TECHNIC OF OPERATION

After the parts have been shaved, three coats of 3.5 per cent. iodin are applied, each coat being fanned dry. This is essential, as it in a measure prevents blistering. The incision, about 2 inches long, is made rather to the outer lateral aspect of the affected side and high up. I find that in this location the skin heals more rapidly. The incision should extend through the skin only, and this dissected back for a quarter of an inch to give room for the mattress sutures. The dartos, cremasteric fascia and muscle are now opened down to the parietal layer of the tunica vaginalis, and the edges are caught in clamps. With the finger, any adhesions between these layers and the tunica are broken up; then the testicle with its tunica covering is peeled out intact, care being taken to free all adhesions up to the cord structures. The cavity of the dartos is packed with gauze to control any oozing. The tunica is opened and the old bottle operation done, care being taken not to strangulate the cord structures. The globus minor is punctured in several places with a cataract knife. If pus appears, the opening is enlarged with fine pointed forceps, and a drain consisting of a piece of rubber tissue sewed to make a tube is inserted in the hole and held in place with forceps, which will aid in replacing the testicle, the forceps to be removed after closure of the dartos. The gauze is removed from the cavity of the dartos and the testicle is replaced, the drain coming out at the upper end of the wound. The dartos and the cremasteric structures are closed with continuous plain catgut. The closure of the skin I consider quite important. This is done by mattress sutures of silkworm-gut about one-quarter inch from the margin of the wound and pulled up tight. Two sutures are usually sufficient. The drain is removed in from forty-eight to seventy-two hours, and the stitches are taken out in six or seven days. In dressing, one should not attempt to irrigate through the drain. Gentle pressure from below will get rid of any accumulation. A suspensory bandage is worn for several weeks.

RESULTS

The results have been so uniformly good and the recoveries so rapid that I believe the operation should be done in all cases, and I suggest the following of the technic as given.

I have had only one case of epididymitis referred to me since being here that could not be traced to gonorrheal origin. The pus at operation, and subsequently, showed by culture *Staphylococcus aureus* infection, the source of which could not be determined.

TUBERCULIN AS A DIAGNOSTIC TEST OF TUBERCULOSIS IN MAN

L. M. RYAN, B.S., M.D.
BANNING, CALIF.

When one delves into the vast amount of bewildering literature that represents the present day knowledge of tuberculins, one is apt to emerge with a chaotic idea, if any at all, of the entire matter. From this literature I have made selections, and have arranged the matter in the way in which it makes the subject clearest to me. I present it here as it applies to diagnostic tests.

Before taking up the subject matter I will give son definitions of terms used, in accordance with my plai

Antituberculin.—A substance found in the blood ar tissues (Ludke, 1907) of a tuberculous person aft being treated with tuberculin. In this connection th would also be called *substance sensabilitrice,* antibod or amboceptor.

Antigen.—The exciting agent — in this case, th injected or applied tuberculin.

Complement.—A protective substance found in no mal blood serum. Its union with the foregoing fa tors has been found to be necessary to produce th bacteriolysis, a step, a factor, perhaps the essenti factor to the production of immunity.

Tuberculin.—A substance consisting of the cultur fluid in which tubercle bacilli have grown, of groun up tubercle bacilli or of extracts of their bodies, an of both combined.

The tubercle bacillus, as other bacteria, claims tw different poisonous substances: (1) exotoxins, or poi sons secreted by the organisms into the cultur medium, and (2) endotoxins, or poisons contained i the living protoplasm of the organism, and liberate only by their disintegration. Tuberculins, whethe from the filtrate or the bacillary body, always produc essentially the same effects, there being differences in the degree, but never in the character of the reactions. They act as the living tubercle bacilli minus the power of growth and reproduction. The tuberculins from human and bovine bacilli are practically the same in their action on infected animals (Weber and Dieterlen).

THE TUBERCULIN REACTION

This is manifested in three ways: local, at point of injection; focal, at location of diseased area, and constitutional, or general body phenomena.

The tuberculin test, in the absence of complete evidence, probably owes its activity to the presence of a specific protein of the tubercle bacillus, either in solution, as bacillary bodies, or as particles of such. In the broad sense, then, tuberculin hypersensitiveness is undoubtedly closely related to the phenomenon of protein hypersensitiveness or anaphylaxis.

Wassermann and Bruck, modifying a theory of Ehrlich's on the modus operandi of the tuberculin reaction, have advanced the following view:

They look on the reaction as depending on a union *in the lesion* of the injected tuberculin with a substance they call antituberculin. The combination anchors a large amount of complement, which acts as a ferment on the surrounding tissue, causing the inflammatory changes characteristic of the focal reaction, these in turn determining the fever and other constitutional symptoms.

The failure of a tuberculous person to react after receiving a large dose of tuberculin may, therefore, be explained in one of two ways, dependent in part on the stage and character of the disease: (1) In mild cases it is presumed that sufficient antituberculin is present in the serum to unite immediately with the tuberculin injected, the speedy combination preventing the local disturbance and keeping the tuberculin from reaching the tuberculous focus. (2) In advanced or severe cases, it is assumed that, owing to the exhaustion following on long stimulation, the cells can no longer furnish the antibodies.

In the same manner, in a latent case there may be a better reaction to a second test than to the first one,[1] and, on the other hand, in a severe case a better reaction to the first one. The following formulas illustrate the working of the theory:

1. Reaction = tuberculin plus antituberculin at focus.
2. No reaction (severe cases) = tuberculin plus no antituberculin at focus.
3. Reaction at first test and better reaction at second = Tuberculin plus plenty of antituberculin at focus; more antituberculin formed as a result of the first dose.
4. Reaction at first test and none at second = tuberculin plus no antituberculin at focus.
5. Tuberculin tolerance (no reaction) = speedy uniting of tuberculin and antituberculin before reaching focus.

The Wolff-Eisner theory explaining the tuberculin reaction is also very ingenious. According to this view, abundant specific lysins are elaborated in a stimulated tuberculous individual. These lysins disintegrate any tubercle bacillus protein later introduced into the individual. In the disintegration process he holds that endotoxins are set free which act as poisons on the tissue cells exposed.

Working with this theory, one would account for the local disturbance or reaction as similar to that occurring in the focus. Hamman and Wolman believe that profound changes exist in all cells of the body of a tuberculous individual. The only remaining factors, then, in the production of the local reaction would be the traumatism to the body cells at the point of application of the tuberculin, and the fact that the tuberculin is concentrated on the same cells. This view is supported by the fact that at the site of the local reaction the tissues show the histologic picture of a tubercle.

COMPARATIVE DIAGNOSTIC TESTS IN MAN

In order of efficiency, these are generally accepted as follows:

1. Intracutaneous: 0.05 c.c. of old tuberculin in a dilution of from 1:1,000,000 to 1:100, if necessary.
2. Subcutaneous: local (old tuberculin).
3. Cutaneous (von Pirquet): 90 per cent. efficiency.
4. Subcutaneous.
5. Percutaneous: old tuberculin and lanolin (Moro test); 83 per cent. efficiency.
6. Conjunctival: 1 per cent. old tuberculin; less efficient than the Moro test.

If we realize that the intracutaneous and subcutaneous tests require absolutely perfect technic and are rather harder to perform and take more time, it would leave by elimination Test 3, the cutaneous, as being the most practical. If, again, we may do anything to make the cutaneous test still more efficient, it will certainly be the most practical.

Detre, in 1908, described his modification of the von Pirquet test, and it is with this that I wish to deal. The tuberculins that he employed were (1) human old tuberculin (H. O. T); (2) human bouillon filtrate (H. B. F.), and (3) bovine bouillon filtrate (B. B. F.).

He employed a small, dull instrument like a jeweler's screw driver, rotated it, made four abrasions on the inner side of the upper arm, and inoculated the three solutions into three of the abrasions, leaving the fourth sterile for control. His idea was that, performed as outlined, it would be a differential diagnostic test, and as such it is known and marketed here and abroad.

This test is supposed to show seven important things in addition to the von Pirquet test: whether the lesion is acute or chronic, active or latent, and whether the infection is of the human or bovine type, or both mixed. By measuring the resultant papules in both diameters in millimeters, he asserts that he is able to judge accurately the process to be determined. His theory is that a person infected with the bovine infection will react more strongly to the bovine filtrates than to the human, and vice versa. Also, a person with the active form of the disease will yield to the filtrate a papule as large as or larger than it will to the old tuberculin, and vice versa with the latent cases.

That the human type may give a predominant reaction, and the bovine some reaction, he attributes to certain of the similar characters of both bacilli, as I have mentioned before. He believes that the predominance of the reaction to the filtrate in active cases is due to the presence in the filtrate of a thermolabile substance that is destroyed in the reduction by heat in the manufacturing of old tuberculin. The body is quickly sensitized to this substance, which is a toxin during the progress of a lesion, and with its arrest auto-immunization to this toxin occurs. He considers auto-immunization to the protein bodies of the old tuberculin a rarer and more difficult occurrence. Many competent observers have tried out his method, and their results are not in harmony. The majority of those who employ or try out this method make a still further modification of Detre's original method. They add the bovine old tuberculin, which, with the control, makes a five abrasion test. They place all cases in eight groups as follows:

Group 1. Human old tuberculin papule positive; others slight or negative (old human lesion).

Group 2. Human old tuberculin papule more marked than human bouillon filtrate papule (old human lesion).

Group 3. Human bouillon filtrate papule more marked than human tuberculin papule (active human lesion).

Group 4. Bovine old tuberculin and bovine bouillon filtrate papules positive, bovine old tuberculin papule more so; others slight or negative (old bovine lesion).

Group 5. Same as Group 4, but bovine bouillon filtrate papule more marked than bovine old tuberculin papule (active bone lesion).

Group 6. Human old tuberculin and bovine old tuberculin papules equal and more marked than human bouillon and bovine bouillon filtrate papules (old mixed lesion).

Group 7. Human bouillon filtrate and bovine bouillon filtrate papules equal but more intense than human old tuberculin and bovine old tuberculin papules (active mixed lesion).

Group 8. All papules approximately alike.

Hamman and Wolman[2] and others have not been able to substantiate this finely drawn classification.

---

[1] In a series of 129 children, Lindenberg recently found that 33 per cent. reacted better to the second test than to the first one. This majority consisted mostly of latent cases.

[2] Hamman, Louis, and Wolman, Samuel: Tuberculin in Diagnosis and Treatment, New York, D. Appleton & Co., 1912.

I myself do not believe that Detre's grouping, even with the modification by addition of the bovine old tuberculin, can be substantiated. Also, I am in some doubt as to whether a patient reacting only to the bovine tuberculins necessarily has a bovine infection. However, the test is generally acknowledged to be fairly accurate in determining whether or not a tuberculous infection, which may be only a trace, is present (accuracy above 90 per cent.); furthermore, if the inoculations are made with the four tuberculins mentioned below, I believe the test can be shown to have much value from a practical standpoint, (1) in detecting the presence of active or clinical tuberculosis; (2) in determining the amount of resistance of the patient, and (3) in offering aid in the treatment.

METHOD OF APPLICATION

The arm, preferably the external surface of the upper arm, is cleansed with ethyl alcohol. Through the superficial part of the skin, five abrasions are made, deep enough to remove the skin, but not to draw blood. These abrasions are made with a small instrument similar to a jeweler's screw driver, by lightly boring with it into the skin. The abrasions should be about three-fourths inch apart and range in a longitudinal straight line parallel with the long axis of the humerus.

After the alcohol is thoroughly dried on the arm, the points are treated from above downward in the following or any similar order one may wish to devise to use as a systematic method:

1. Human old tuberculin.
2. Human bouillon filtrate.
3. Bovine old tuberculin.
4. Bovine bouillon filtrate.
5. Not inoculated; kept as control.

After two or three minutes the excess tuberculin is blotted off with a piece of sterile gauze and the sleeve pulled down without the application of any dressing.

The various tuberculins enumerated may be best purchased in 1 c.c. vials from some standard maker of biologic products. For ease of application, a small glass rod may be shoved through each cork. In the process of inoculation, the abrasions are merely touched, each with the individual tuberculin, enough being placed on to cover, but not to run and contaminate the tests. To avoid contamination of the solutions, the glass rod should be sterilized in a flame after each inoculation.

AFTER-APPEARANCE OF TEST POINTS

Soon after the boring, a small mechanical wheal forms. Within from four to twenty-four hours in most cases after inoculation, a small red papule forms at the various areas in which the reaction will take place. These, in the more severe reactions, advance to the vesicular stage.

In some cases the point of reaction does not reach its greatest size for forty-eight hours or more. From then on there is a gradual diminution of size and fading of color of the papule, until at the end of approximately a week a small bluish mark is all that remains.

Constitutional symptoms are rare.

Of course, in the use of this test, as in others, nearly all persons will react after thirty-six hours (the so-called latent cases of tuberculosis). It would seem, therefore, that the importance of this test depends on the amount of reaction within the first thirty-six hours. One soon becomes accustomed to various sized papules as depending on the amount of reaction and the supposed amount of activity of the disease that causes them.

AMOUNT OF REACTION

Detre used a measurement of 5 mm. in each diameter or over in the size of the papule as meaning a positive reaction. It would seem that the size and field of the scarifier would enter into this so largely that such a classification could not be accurate. The following classification seems more practical:

Any redness more than control, +.
More redness with some infiltration, ++.
More redness yet and a wide area of infiltration, cases that go on to vesiculation, +++.

The tuberculin test is specific. Persons who do not have tuberculosis will not react to tuberculin. This has been proved finally after many investigators were ready to discard the test as an inaccurate procedure, undoubtedly because of their contrariness of technic and interpretation of experiments.

There are conditions of tuberculin insensitiveness in which tuberculosis is present and the test shows negative:

1. In conditions in which there is great toxemia and consequently no antibodies, the test will show as a negative. This condition is perhaps the one encountered most often giving a negative, yet this happens rarely, considering the number of cases in which there is a reaction. It will depend a great deal on the source of the cases. In some county and state institutions, it may be as high as 10 per cent. or more; but as a rule 2 per cent. will cover it.
2. Completely healed lesions will not react.
3. Often pneumonia, diphtheria, scarlet fever, or cerebrospinal meningitis may mask a tuberculous condition that may also be present.
4. In very acute tuberculous infections, as acute miliary tuberculosis, tuberculous meningitis, or very rapidly progressing pulmonary tuberculosis, the test may be negative.
5. Errors in technic should be very rare with the modified Detre test.
6. Tuberculin treatment produces, if successful, a condition of antianaphylaxis.

ADVANTAGES

This test, which is largely in use in this section of the country, should be used in every examination made to discover the presence of active tuberculosis.

1. It is easy in application.
2. It is of some value in prognosis. Its absence in a case of known tuberculosis would indicate considerable doubt as to the recovery of the patient. Of course, this does not mean that every patient who reacts will recover. In a very latent case there is only a slight reaction. A case with a marked reaction would tend to show, taken with other signs and symptoms, a marked resistance, although also showing marked activity. These points in prognosis I merely mention as examples, and in this paper I cannot elaborate them.
3. Constitutional disturbances accompanying the test are very rare.

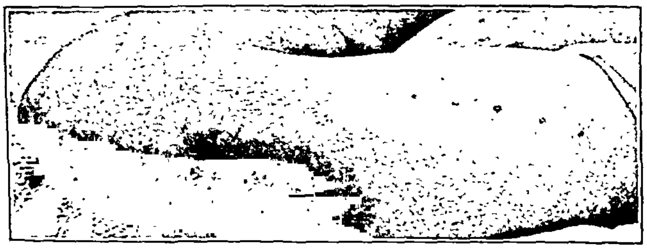
4. Its efficiency might be thus elaborated: Many observers say that an exclusively bovine reaction means a bovine infection. They bring in findings of this in from 0.6 to 25 per cent. of their cases, depending greatly on the localities. We could safely substantiate 4 per cent. in our large cities of the Southwestern States.

A certain percentage also show filtrates positive when the old tuberculins are negative.

In Dr. Browning's series at the Los Angeles County Hospital, in 1,482 cases up to the spring of 1917, there were 781 positive reactions to human old tuberculin; 725 to human bouillon filtrate; 722 to bovine old tuberculin, and 691 to bovine bouillon filtrate. Less than 200 did not react. This quantity is easily explained by the class of cases as a rule in such institutions. As Dr. Browning says:

> Unless all are used [meaning modified Detre] certain cases will be met with in which the desired information would not be obtained, as evidenced by the difference between the 781 H. O. T., which is the von Pirquet test, and the 1,482 less the number which was 200 or less, which did not react to either.

If the various statistics will give the von Pirquet or our No. 1 of this modified Detre 90 per cent. efficiency, and to this we add the cases responding only to the bovine tuberculins and filtrates, it would seem that this test would be just about as efficient as the subcutaneous local or the intracutaneous test; and when we consider the ease of application with the much lessened chance of technical errors, I believe that this is our best tuberculin test that has been worked out to date.[3]



Appearance of arm with test applied; strongest reaction at third scarification, the predominant reaction in this type of case to bovine old tuberculin.

Trap Shooting as a Recreation for Physicians.—Dr. Leroy A. Newton recommends trapshooting as a recreation for physicians—perhaps as a substitute for golf. Among the unassailable reasons why this form of outdoor sport is peculiarly adapted to physicians he enumerates the following: Trapshooting and sociability are inseparable, and the one great thing that elevates man above the other animals is sociability; it takes the physician away from all business and affords complete relaxation from professional cares; it is an outdoor game with a goodly amount of exercise connected with it; it will make a man cut out bad habits, as trapshooting and bad habits cannot go together; many men train for a tournament as carefully as does the prizefighter, leaving off tea and coffee, alcohol and tobacco, eating plain food and paying attention to proper elimination. Age is no bar. It will keep the devotee physically fit, Newton says, and make a better man of him in every respect.

OBSTRUCTIVE DYSMENORRHEA AND STERILITY

A NEW OPERATION

JACOB FRANK, M.D.
CHICAGO

Obstructive dysmenorrhea and sterility most commonly depend on a pathologic anteflexion of the uterus. One must lay emphasis on and distinguish such an anteflexion, as opposed to the physiologic anteflexion of the normal uterus, if one is to get successful results from any corrective measures that may be instituted. With the distinction between the physiologic and pathologic anteflexions clearly in mind, I wish to present an operation for the correction of the

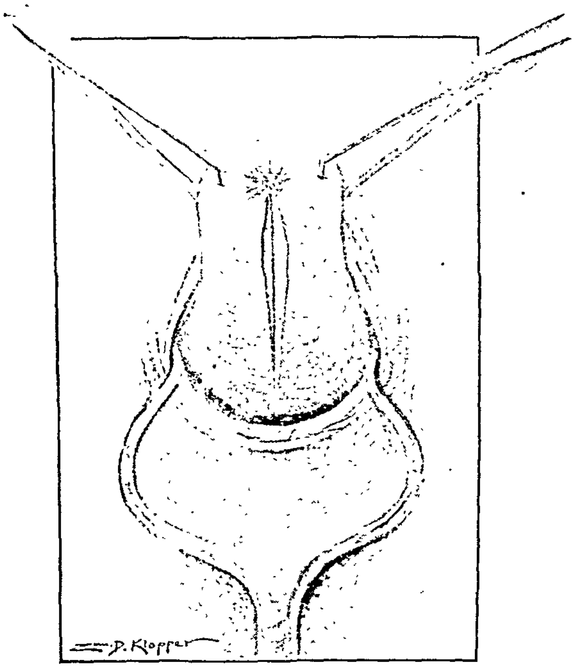

Fig. 1.—Uterus brought forward and upward; posterior incision begun.

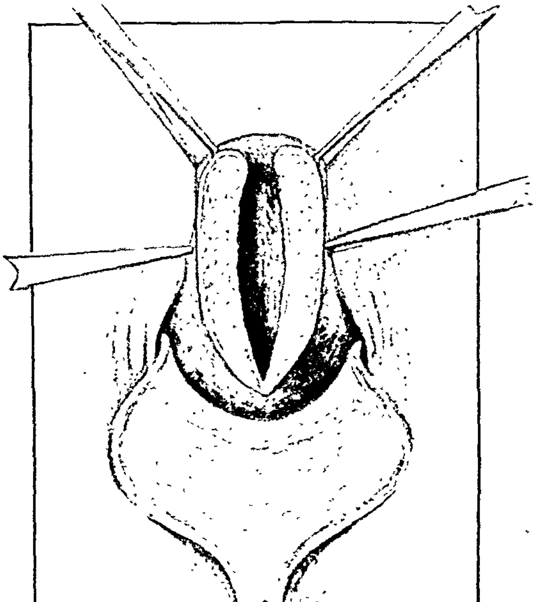

Fig. 2.—Incision completed, showing two lateral raw surfaces.

I myself do not believe that Detre's grouping, even with the modification by addition of the bovine old tuberculin, can be substantiated. Also, I am in some doubt as to whether a patient reacting only to the bovine tuberculins necessarily has a bovine infection. However, the test is generally acknowledged to be fairly accurate in determining whether or not a tuberculous infection, which may be only a trace, is present (accuracy above 90 per cent.); furthermore, if the inoculations are made with the four tuberculins mentioned below, I believe the test can be shown to have much value from a practical standpoint, (1) in detecting the presence of active or clinical tuberculosis; (2) in determining the amount of resistance of the patient, and (3) in offering aid in the treatment.

METHOD OF APPLICATION

The arm, preferably the external surface of the upper arm, is cleansed with ethyl alcohol. Through the superficial part of the skin, five abrasions are made, deep enough to remove the skin, but not to draw blood. These abrasions are made with a small instrument similar to a jeweler's screw driver, by lightly boring with it into the skin. The abrasions should be about three-fourths inch apart and range in a longitudinal straight line parallel with the long axis of the humerus.

After the alcohol is thoroughly dried on the arm, the points are treated from above downward in the following or any similar order one may wish to devise to use as a systematic method:

1. Human old tuberculin.
2. Human bouillon filtrate.
3. Bovine old tuberculin.
4. Bovine bouillon filtrate.
5. Not inoculated; kept as control.

After two or three minutes the excess tuberculin is blotted off with a piece of sterile gauze and the sleeve pulled down without the application of any dressing.

The various tuberculins enumerated may be best purchased in 1 c.c. vials from some standard maker of biologic products. For ease of application, a small glass rod may be shoved through each cork. In the process of inoculation, the abrasions are merely touched, each with the individual tuberculin, enough being placed on to cover, but not to run and contaminate the tests. To avoid contamination of the solutions, the glass rod should be sterilized in a flame after each inoculation.

AFTER-APPEARANCE OF TEST POINTS

Soon after the boring, a small mechanical wheal forms. Within from four to twenty-four hours in most cases after inoculation, a small red papule forms at the various areas in which the reaction will take place. These, in the more severe reactions, advance to the vesicular stage.

In some cases the point of reaction does not reach its greatest size for forty-eight hours or more. From then on there is a gradual diminution of size and fading of color of the papule, until at the end of approximately a week a small bluish mark is all that remains.

Constitutional symptoms are rare.

Of course in the use of this test, as in others, nearly all persons will react after thirty-six hours (the so-called latent cases of tuberculosis). It would seem, therefore, that the importance of this test depends on the amount of reaction within the first thirty-six hours. One soon becomes accustomed to various sized papules as depending on the amount of reaction and the supposed amount of activity of the disease that causes them.

AMOUNT OF REACTION

Detre used a measurement of 5 mm. in each diameter or over in the size of the papule as meaning a positive reaction. It would seem that the size and field of the scarifier would enter into this so largely that such a classification could not be accurate. The following classification seems more practical:

Any redness more than control, +.
More redness with some infiltration, ++.
More redness yet and a wide area of infiltration, cases that go on to vesiculation, +++.

The tuberculin test is specific. Persons who do not have tuberculosis will not react to tuberculin. This has been proved finally after many investigators were ready to discard the test as an inaccurate procedure undoubtedly because of their contrariness of technic and interpretation of experiments.

There are conditions of tuberculin insensitiveness in which tuberculosis is present and the test shows negative:

1. In conditions in which there is great toxemia and consequently no antibodies, the test will show as a negative. This condition is perhaps the one encountered most often giving a negative, yet this happens rarely, considering the number of cases in which there is a reaction. It will depend a great deal on the source of the cases. In some county and state institutions, it may be as high as 10 per cent. or more; but as a rule 2 per cent. will cover it.
2. Completely healed lesions will not react.
3. Often pneumonia, diphtheria, scarlet fever, or cerebrospinal meningitis may mask a tuberculous condition that may also be present.
4. In very acute tuberculous infections, as acute miliary tuberculosis, tuberculous meningitis, or very rapidly progressing pulmonary tuberculosis, the test may be negative.
5. Errors in technic should be very rare with the modified Detre test.
6. Tuberculin treatment produces, if successful, a condition of antianaphylaxis.

ADVANTAGES

This test, which is largely in use in this section of the country, should be used in every examination made to discover the presence of active tuberculosis.

1. It is easy in application.
2. It is of some value in prognosis. Its absence in a case of known tuberculosis would indicate considerable doubt as to the recovery of the patient. Of course, this does not mean that every patient who reacts will recover. In a very latent case there is only a slight reaction. A case with a marked reaction would tend to show, taken with other signs and symptoms, a marked resistance, although also showing marked activity. These points in prognosis I merely mention as examples, and in this paper I cannot elaborate them.
3. Constitutional disturbances accompanying the test are very rare.

The original Pozzi operation is ideal in cases of true "pin-hole os," that is, for obstruction at the external os. But in many cases the dysmenorrhea and sterility result from angulation of the uterocervical canal at or near the internal os. And my experience leads me to believe that angulation never takes place above the internal os. This angulation is completely done away with by the operation described, by eliminating entirely the canal below the angulation, as the posterior incision extends up to and beyond this point.

I would not hesitate to apply the principle of this operation for retroflexion of the uterus producing symptoms, should the proper case present itself.

ELEPHANTIASIS

REPORT OF A CASE

REINHARD E. WOBUS, M.D.
AND
E. L. OPIE, M.D.
Professor of Pathology, Washington University Medical School
ST. LOUIS

Cases of elephantiasis are sufficiently rare in this climate to warrant the reporting of all observed cases. It is for this reason that we submit the following case report:

REPORT OF CASE

History.—Miss C., aged 40, a domestic, born in southern Germany, her name indicating French descent, had come to this country in early childhood and had lived in St. Louis without intermission since. She had the usual diseases of childhood, but otherwise had enjoyed good health.

At an early age, her mother experienced increasing difficulty in fitting her right shoe, the right foot being apparently somewhat swollen. Since then the right foot had progressively enlarged, the swelling gradually affecting the leg. She was placed under the care of Dr. H. H. Summa, who had since had her under observation. He made the diagnosis of elephantiasis of unknown origin, and tried various methods of combating it, among them bandaging with elastic bandages and potassium iodid. The condition became gradually worse, it became increasingly difficult to have proper footwear fitted, the muscles became progressively weaker and, with the increasing weight of the tumor, locomotion became difficult. Therefore, physician and patient agreed on amputation.

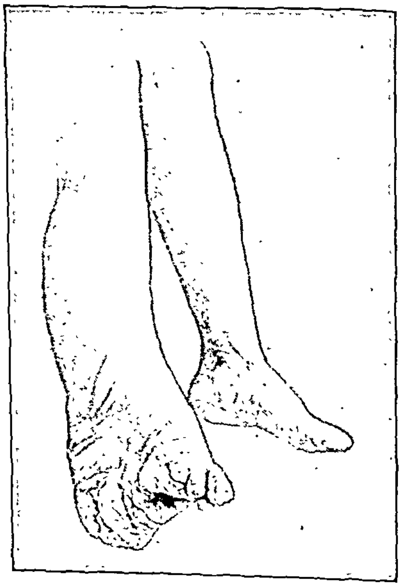

Fig. 1.—Elephantiasis.

Operation and Result.—While various operations for resection of the diseased tissue (decortication) with plastic reconstruction of the soft parts have been proposed, with apparently fair success, the extent of the trouble and the involvement of the musculature seemed to rule out this mode of procedure. Ligature of the femoral artery did not seem to promise any great relief. Hence we did an amputation high enough to get into healthy tissue. Five years have now elapsed, and there has been no extension of the process. The patient walks around well on her artificial leg, and is happy to have been relieved of her tumor mass.

EXAMINATION OF SPECIMEN, BY DR. OPIE

Gross.—The specimen consisted of the lower leg amputated just below the tubercle of the tibia. The leg was deformed by a pendulous mass occupying the entire calf, heel and sole of the foot to within 10 cm. of the toes. The lower part of the leg and the foot, except the toes, were obscured by a mass which, over the lower third of the leg, completely surrounded the bones. The tissue was nodular and soft, and the dependent part appeared to be edematous. The skin was soft and freely movable over the underlying constrictions. On section through the calf, extended into the pendulous tissue about the heel, it was found that the enlargement was due to the presence of a mass of white tissue which was tough and fibrous. Ill defined nodules were visible and palpable within it. The gastrocnemius muscle was pale and marked with opaque striations. The mass over the heel was of the same structure. The white fibrous tissue invaded the fat over the heel and the sole of the foot. It was intimately bound to the periosteum of the os calcis. The tumor seemed almost completely to have replaced the gastrocnemius. Red muscle of fairly normal appearance was reached only when the section had penetrated through the calf to the bones. In places, what appeared to be blood vessels were surrounded by an unusually firm layer of fibrous tissue.

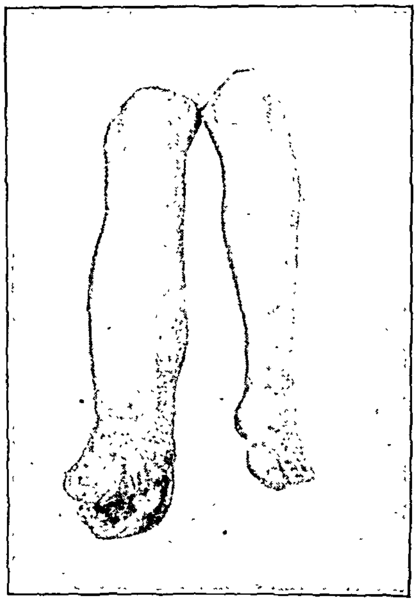

Fig. 2.—Elephantiasis.

Microscopic.—On section through the skin the corium was occupied by a dense, fibrous, scarlike tissue, continuous with the underlying subcutaneous tissue, which had in many places been converted into dense fibrous tissue poor in cells; but immediately above the blood vessels, it contained numerous cells of the connective tissue type. Mononuclear eosinophil cells were fairly numerous. The tissue underlying the skin for a distance of more than 2 cm. consisted of islands of fat surrounded by dense fibrous tissue. Around the blood vessels, new formed tissue was often especially dense. The intima was greatly thickened, and the media was traversed by fibrous tissue.

Sections from many parts of the leg were examined. They consisted of dense fibrous tissue, in a few places containing cells in abundance. A section from the voluntary muscle showed that it was being replaced by a new formed fibrous tissue. In some places, muscle cells were replaced by fat; in others, by masses of fibrous tissue.

The diagnosis was elephantiasis.

Comment.—The section offered no explanation of the cause of the condition. The lymphatic vessels showed no dilatation, and were inconspicuous in the section. The lesion may be classed as elephantiasis dura.

Apparatus for Artificial Respiration.—A. L. da Cunha gives an illustrated description in the *Revista Medico-Cirurgica do Brazil,* 1917, **25**, 276, of an electric device for artificial respiration. It combines rhythmical traction of the tongue with intratracheal insufflation of oxygen.

down to the bone is made across the nose between the eyes where the bridge of a pair of glasses would rest. With small, blunt, curved eye scissors a pocket is made in the midline of the nose down to the tip. Care must be taken to keep the pocket in the midline and not to enter the nasal cavity. The piece of celluloid which will best correct the deformity is selected from those previously prepared, and if any trimming is needed, it is placed in hot water, when it may be cut with a knife as readily as cartilage; on cooling it becomes hard again. If it is necessary to curve the implant, placing it in hot water makes this possible, and it should be held in the required position until it is cooled.

After the celluloid has been shaped, it is inserted down to the tip of the nose; the wound is closed with horsehair and sealed with tincture of benzoin compound. A thin copper splint is applied externally and held in place by adhesive plaster. In all the five cases the wounds healed primarily with practically no reaction. The implants have remained in position and have given no trouble; some of them have been in place for more than a year. I have not had an opportunity to use celluloid in a flap operation, but see no reason why it could not be thus used.

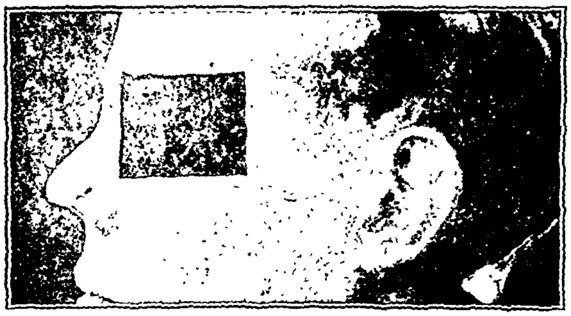

Fig. 6 (185775).—After insertion of celluloid into tissue over the nose.

CONCLUSIONS

It would seem from my experience with these cases that celluloid has several advantages as an implant in the correction of nasal deformities.

RESULTS OF EXPERIMENTS

		Series No.	Time After Operation	Results
		1	138 days	On palpation the celluloid could be felt in position and could not be displaced; when the celluloid was exposed it was found to occupy a definite pocket, but organization had not completely taken place through the perforations; the celluloid was easily removed; the tissue about the celluloid showed no inflammatory reaction; the implant was not altered in any way
76-17	B-530	2	168 days	The celluloid was still in position, but was surrounded with pus; the material itself appeared to be the same as when embedded
77-17	B-684	3	365 days	On palpation the celluloid could be felt in position, but could not be displaced; when the celluloid was exposed it was found to occupy a definite pocket, and its upper end was embedded in bone; the tissue over the celluloid was incised, and definite finger-like processes of tissue were found to extend through each perforation; the implant could not be removed until these were cut; the tissue about the celluloid showed no inflammatory reaction, and the implant was not altered in any way
392-17	B-980	4	Unknown, at least 120 days	The site of the implant became infected, and the celluloid came out
393-17	B-981	5	211 days	On palpation, the celluloid could be felt in position and could not be displaced; when the celluloid was exposed, it was found to occupy a definite pocket, but organization had not completely taken place through the perforations; the celluloid was easily removed; the tissue about the celluloid showed no inflammatory reaction; the implant was not altered in any way
394-17	B-982	6	219 days	On palpation, the celluloid could be felt in position and could not be displaced; when the celluloid was exposed, it was found to occupy a definite pocket, but organization had not completely taken place through the perforations; the celluloid was easily removed; the tissue about the celluloid showed no inflammatory reaction; the implant was not altered in any way

1. It eliminates the necessity of taking an autogenous transplant.
2. It causes practically no reaction when inserted in the tissues, and apparently is not affected by them.
3. It may be readily trimmed or curved when placed in hot water.
4. It remains stiff even when trimmed quite thin.

Military Medicine and Surgery

A SIMPLE FACE MASK FOR USE BY CONTAGIOUS DISEASE ATTENDANTS

ARTHUR M. DANNENBERG, M.D.
First Lieutenant M. R. C., U. S. Army
CAMP JACKSON, COLUMBIA, S. C.

Modern scientific investigation has definitely established that the most frequent mode of transmission of infectious diseases is through droplet infection from the oral and nasal passages of the infected persons or unrecognized carriers of the infectious organisms. A recognition of this fact has caused the adoption at the base hospital, Camp Jackson, S. C., particularly by the physicians and other attendants of the cerebrospinal meningitis patients, of various forms of protective face masks. The one most commonly used is a gauze strip, made either of several layers of gauze bandage or more frequently of a gauze dressing roll, which covers the nose and mouth and is held in place at the occiput by a pin or a knot.

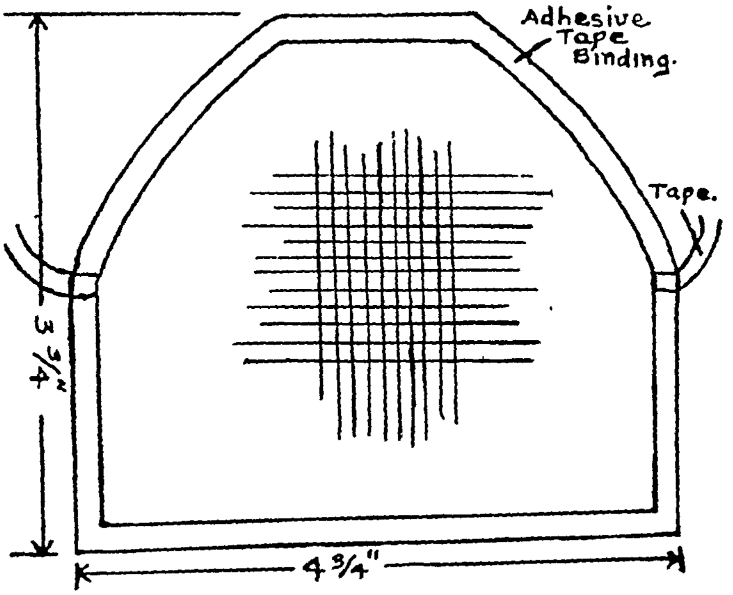

Fig. 1.—Diagram for construction of face mask.

This method entails the use of large quantities of gauze, and has proved generally unsatisfactory since it is uncomfortable, rarely remains in position, and causes fogginess of the eyeglasses.

In recognition of the limitations of the gauze strip, a simple mask meeting every requirement of protection and comfort was designed.

It is made as follows:

A piece of galvanized wire mesh, generally used for screening purposes, is cut as in Figure 1. The size varies with the requirements of the individual physiognomy. The measurements indicated in Figure 1 are for the average male face. The edge of the mask is bound by adhesive plaster to protect the face from the wire points that are present. A piece of tape is then sewed in the center of both sides directly through the wire and adhesive binding.

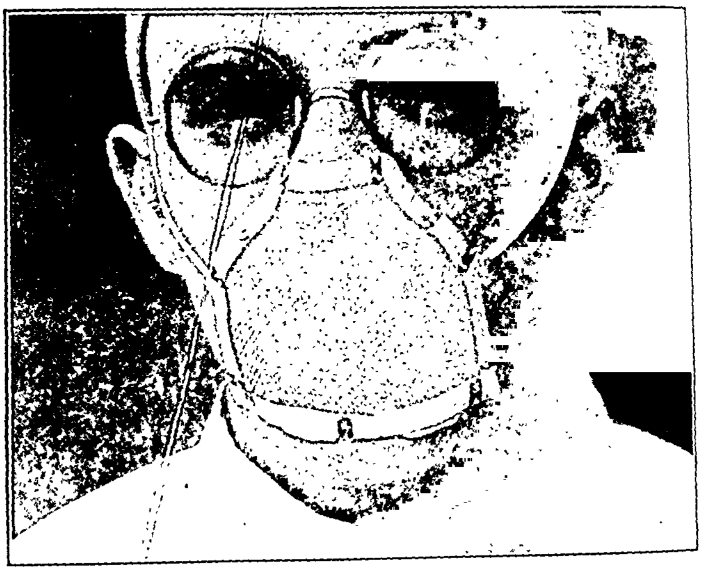

Fig. 2.—Front view of face mask.

Gauze, usually of double thickness, is cut one-quarte inch larger than the mask and placed on the latte with its edges turned under to prevent fraying. Th gauze is then sewed either directly to the mask, o fastened by means of brass paper clips. The clip permit rapid replacement of the gauze when neces sary. The mask is then molded to fit comfortabl over the nose and mouth, and is held in position b the pieces of tape, which are brought over the ea and tied under the occiput.

To facilitate the putting on of the mask, its quic removal, or its better adjustment on the face, a elastic tape may be used in lieu of the nonelastic on

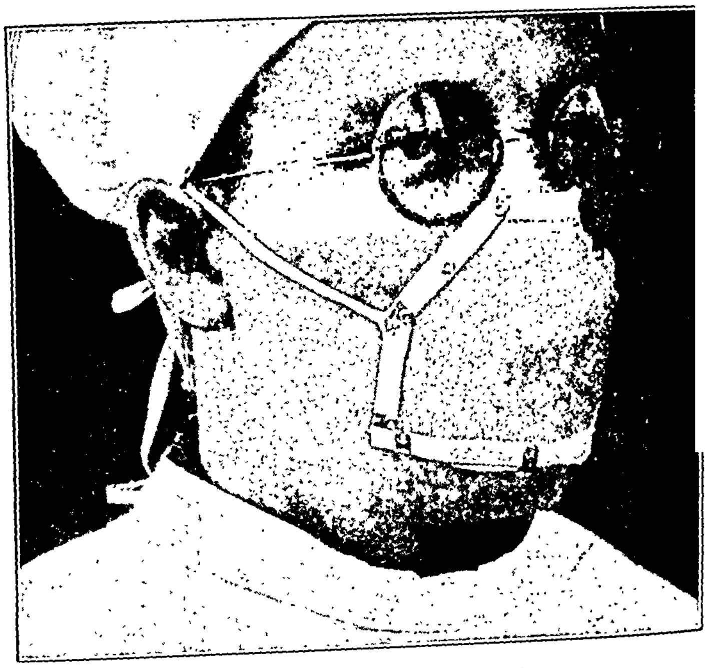

Fig. 3.—Side view of face mask.

The advantages of this mask are: (1) complete protection; (2) simplicity; (3) ease of manufacture; (4) economy in the use of gauze; (5) ability to wear it without the eyeglasses becoming foggy, and (6) permanence of position on the face.

VISUAL FACTORS IN EQUILIBRATION, ESPECIALLY AVIATION

PERCY FRIDENBERG, M.D.
Attending Ophthalmic Surgeon, Lebanon Hospital; Junior Surgeon, New York Eye and Ear Infirmary
NEW YORK

The great importance of aerial flight in modern warfare, and the need of full information as to the *functional integrity* of aviators, has shown how a practical demand in medical science can almost immediately produce a supply in the standardization and application of labyrinthine tests which until comparatively recently were, if not quite theoretical, at least not applied so uniformly, generally and accurately as to become a routine measure of value. At present, the rotational tests can be carried out in less than a half hour, and the vertigo, past pointing and falling, in fact, the entire labyrinthine reaction, determined and recorded. This is due largely to the use of a standard chair that can be stopped on the second and rotated evenly at a given speed, and to the control of all tests with the stop watch. It has generally been assumed that a normal labyrinth is the sine qua non and the only essential for equilibration. It seems to me that this is a one sided point of view, that there are other important factors of equilibrium, and that visual factors, particularly, have been overlooked and merit attention in the determination of physical fitness of applicants for positions in the flying corps.

Without any intention of denying the importance of labyrinthine integrity or of belittling the practical tests of *function by rotation*, I believe it is timely to sound a note of warning against the neglect of other factors in balance and vertigo, and to call attention to the practical significance of clear vision and normal ocular muscle balance in aviators and military recruits. The labyrinthine tests refer, naturally, to rotational vertigo alone, and the fallacy to which I wish to call attention is the view that all vertigo is rotational and, so, labyrinthine. As a matter of fact, we must recognize, as did Nagel years ago, that there is a continuous series of vertigo forms ranging from the purely labyrinthine, due to rotation, to the purely visual without any motion or rotation component whatsoever, and that all of these forms are of practical importance as they equally interfere with balance and direction control and with full and undisturbed consciousness. Forms of dizziness that may make one faint or unable to control an aeroplane are commonly found in neurasthenia, anemia, chronic alcoholism, malaria, chronic nicotin poisoning, and many other toxic states, as well as in chronic intestinal indigestion, lead intoxication, and in convalescence from various diseases. Aside from these illnesses, apparently healthy subjects complain of dizziness due to various ocular anomalies, among which I may cite mixed astigmatism, accommodation spasm and paresis, ocular motor imbalance, retinal hyperesthesia, and asthenopic strain from whatever cause, functional, organic or, finally, exterior, as defective or improper illumination, position or work. Faulty or ill fitting glasses, especially prisms or cylinders, are quite sufficient to cause dizziness of incapacitating degree.

Labyrinthine disease is not common, even in hospitals devoted to the ear. Probably only a very small percentage of all mastoid operations involves the inner ear. The patients with labyrinthine involvement are generally critically ill. At least we may be safe in saying that they are not going about in search of positions in the flying corps. The same may be said of dead labyrinths. Their unfortunate possessors are not apt to try lofty flights, ideal or actual; and nowadays that the mastoid operation is performed early and often, the dead labyrinth, generally a result and residuum of neglected chronic labyrinthitis, is becoming progressively rarer. Reference has been made to unexplained falls from flying machines, and it is taken for granted that these accidents have happened to aviators with defective labyrinths, and that they might have been avoided by previous rotational tests.

I think these assumptions quite gratuitous. In the first place, such defective labyrinths would have been detected in the course of instruction over the aviation field, or, at least, during the first trial flights. Again, the assumption ignores the possible effects of altitude and temperature on normal but susceptible organisms — not alone the labyrinth — and the natural possibility, amounting to a great probability, that any one of a dozen factors, such as those enumerated above, and including, besides, cardiac syncope, embarrassed respiration or circulation, and panic fear, could easily cause an aviator to lose control of his machine and come crashing to earth. There must be a great variation in the reaction of normal subjects to the extreme changes of position and balance inseparable from aviation. Looking down from an extreme height, especially when insecurely placed, as on a church steeple or a precipice, and even when on secure footing, as a bridge, and viewing objects in rapid or irregular, motion, such as storm-driven clouds, waves, masses of water tumbling over a fall or pouring through a flume, frequently cause dizziness to the point of complete lack of balance and loss of consciousness (German, Hoehen-Schwindel).

Extreme or irregular stimulation of the organ of vision, dazzling or blinding, again, may cause similar symptoms, and we know well that there are certain *physico-mental* states, such as *retinal asthenopia*, in which even slightly increased stimuli produce markedly abnormal irritation. Irregular illumination and motion of objects alone may cause dizziness and confusions, as seen in the common or field variety of "movie" headache and dizziness. A swinging mirror may cause a most marked sea-sickness, which, itself, the classical example of vertigo, is often relieved most effectually by excluding visual impressions, merely by closing the eyes. It cannot be too often repeated with emphasis that vertigo is a disturbance or partial loss of consciousness due to incongruous reactions, whether of labyrinth, muscle-sense or vision.

Our sense of balance, like our sense of space, is a conception based on complex data; an impression founded on sensory percepts, from three main sources. Confusion, evinced as dizziness or terminating in loss of balance, is the result of incongruity or misinterpretation of the total impression, though not necessarily of the falsity, however striking, of a single factor. Thus, seeing the world upside down or reversed in a mirror, does not disturb our sense of balance or our ideas of space, as we unconsciously make allowance for the new point of view. Compare with this the confusion that follows when we attempt to carry out or control even the simplest motions doubly reflected in a glass instead of under the direct guidance of the eye. It is the discrepancy between the messages from eye, labyrinth and the pressure sense that causes confused states.

As normal labyrinths merely supply the possibility of vertigo and false sensations of direction and space (falling and past pointing), one might even venture the paradox that the safest aviators would be those with dead labyrinths. If we do not seriously go to this length, we at least may call attention to the lack of accurate data as to the nature of body balance under all conditions of rest and motion, and the rôle of the different senses, especially of vision, in its maintenance. Coming down to practical tests, just how much of a handicap is a dead labyrinth for accurate and delicate balancing? The absence of past pointing and of falling would indicate that it is an advantage rather than a drawback. Von Cyon showed, many years ago, that it was absurd to claim that the inner ear gives us accurate information regarding our relation to the vertical or as to our relative position in space. He gives numerous examples of illusions of position in space when we are not corrected by visual, musculocutaneous or splanchnic pressure sensations. The illusion of inclination of external objects viewed from a train when tipping on a curve, or from the inclined plane of a switchback gravity railway, are cases in point. The labyrinth does not teach the average subject when he is holding his head straight, that is, vertical, and the careful observer will note an inclination of from 2 or 3 to nearly 10 degrees in normal persons. The moment they are called on to adjust this error by visual impressions, the head assumes the correct vertical position. In other words, the body position is brought into correspondence with a *visually* sensed standard, in this case a vertical line, or what is just as good for practical correction, one at right angles to it, that is, horizontal. If the standard chosen is false, if the line is not exactly vertical, error will still be manifested. In other words, the labyrinth does not help a bit. In the absence of visual standards for correction, there is no doubt that pressure sensations, especially those in the cervical and lumbar vertebrae, and tonus or innervation stress in the muscles of the neck and back, are constant if almost subconscious data of balance and position. These factors, too, have been almost entirely neglected in favor of a one sided and exclusive attribution to the labyrinth of balance control functions.

Another point as to our instinctive concepts of balance: On terra firma, our changes in position take place in a horizontal plane, our usual balance is lateral, from side to side, and rarely fails. Forward and backward equilibrium is much less secure, and when we fall it is generally in one or the other of these senses. It is in accordance with these sensations that balance confusion or dizziness is usually attributed to false horizontal motion in the subject as well as in the outer world. Our sense of the vertical, it would seem, is called on in a greater degree in aviation. Possibly, also, the vertical semicircular canal plays a more important rôle. It would be instructive to learn whether there is such a thing as rotational vertigo in a vertical, instead of a horizontal, plane. Tumblers and acrobats, as well as bird-men, should be able to tell us something about it.

Within the last few days (from February 10 to 15), a number of aviators have lost their lives at various training camps by falls during trial flights. Undoubtedly these accidents, too, will be attributed to defective labyrinths, although it is to be assumed that by this time all applicants for the flying corps have been examined and put through rotational tests. As there is at least a question whether these tests are sufficient, it might be well to make practical observations of the conditions in flying and their reactions thereto, visual, as well as labyrinthine.

After all, an ounce of practice is worth a pound of theory, and the proof of the pudding is in the eating. In this connection, interest attaches to a letter,[1] from an American aviator in France, describing his own sensations in flight when unable to see, and dependent only on his labyrinthine "balance sense":

> While in the air at about 700 meters some low hanging clouds blew down, enveloping me completely and likewise losing me completely. For a half hour I wandered around vainly trying to get my bearings. . . . When you get into very thick clouds it is impossible to tell whether you are in *ligne de vol*, that is, flying level, for there is no horizon visible to gage on. Frequently, an aviator will come out into clear space and find himself on the verge of a wing slip.[2]

The American method of learning to fly always includes double control. The student rides with the instructor, who can take control away at any time. Therefore they go into the air at once. Under such conditions it should be easy for a trained observer to make notes — if only mental notes — of the pupil's reaction to unusual visual conditions.

While nothing has been said about vision in its relation to flying, a word as to this function may not be amiss. Normal distant vision, determined by test card, as expressed in the formula $^{20}/_{20}$, is, of course, a sensible requirement. There are, however, other factors to be considered, all of which are introduced into the practical problem of aviation, by the fact that sight must be used under very unusual conditions. Thus the question of hypersensitiveness to bright light, the sharpness of the sense of motion — a function of the periphery of the retina that has been studied but little — the acuity of vision in lowered illumination, the appreciation of contrast in form, color and light, all of which have an important bearing on the recognition of distant objects, especially those seen at unfamiliar angles which have no associations in shadow or relief, the rapid and accurate judgment of distance, direction, size, and depending on all of these, pace, make an interesting and practical problem.

---

[1] New York Sun, Feb. 13, 1918.

[2] In other words, his labyrinth was useless as an organ for balance and sense of space.

Inferior Pennyroyal Leaves.—Examination of samples of pennyroyal leaves, *Hedeoma pulegioides* (Linne) has disclosed that in a large number of instances, the product has been very carelessly collected and frequently contains large amounts of sand, stems and other foreign material. From the data at hand, the food and drugs bureau, United States Department of Agriculture, is of the opinion that properly collected pennyroyal leaves should contain not more than 10 per cent. of stems, not more than 16 per cent. of total ash and not more than 6 per cent. of acid insoluble ash (sand). The bureau, therefore, will consider as adulterated, under the Food and Drugs Act, any material which does not meet the demands of these figures. Further investigation may reveal the necessity of establishing a more rigid requirement, in which case due notice will be given. The Department of Agriculture proposes to issue the foregoing service and regulatory announcement concerning pennyroyal, but before doing so asks the opinions of interested persons as to the fairness of the ruling.

GENERAL ANALGESIA BY ORAL ADMINISTRATION *

JAMES T. GWATHMEY, M.D. (New York)
and
HOWARD T. KARSNER, M.D. (Cleveland)
Captains, M. R. C., U. S. Army
FRANCE

This report is in the nature of a preliminary communication based on animal experiments and a sufficient number of clinical cases to support the conclusions of the animal work. It will be seen that general analgesia in which there is loss of sensation, with or without loss of consciousness, can be established for otherwise painful dressings and for short operations. The desirability of such a procedure becomes apparent immediately on entering a military hospital, and it has also a definite place in civil surgery.

Many war wounds are accompanied by fractures of bones, and the importance of keeping such patients quiet is universally recognized. If the dressing of such a wound is accompanied by severe pain, it is customary at this base to produce nitrous oxid-oxygen or light ether anesthesia for at least the first few dressings, necessitating in most cases, because of limitation of apparatus, removal of the patient to the operating room. This usually means pain and the danger of misplacing the bone fragments before and after dressings, as well as loss of time to surgeons, nurses and orderlies. General analgesia, produced simply and quietly without taking the patient from his bed, is the logical solution of this difficulty, and the technic evolved as the result of this study makes it possible to administer the analgesic by mouth in perfect safety. It is, of course, applicable to practically all forms of painful dressings, and is being developed to embrace short surgical operations, such as resection of a rib, removal of foreign bodies, and revision of wounds. In such operations, however, it may be necessary to supplement the analgesia with procain (novocain) for the skin incisions, a hypodermic injection of morphin, or even by light inhalation anesthesia.

Local conditions made it seem advisable to select rabbits as the animals for the preliminary work. The various substances were given by a stomach tube, after which the animals were immediately released and placed under observation.

It must be borne in mind that the experiments outlined in Table 1 were not conducted as experiments on the detailed physiology of analgesia, but simply for the purpose of demonstrating that analgesia can be produced by oral administration of proper agents. As will be seen, various combinations of drugs were not especially successful, and in rabbits the best results were obtained by the use of ether in oil. It was found, however, that this mixture produced an acute gastritis in the animals, but further investigation showed that olive oil alone produced quite as severe a gastritis as when combined with ether. Since olive oil is practically nonirritant to the human stomach, it was considered safe to proceed with the investigation on man. It was thought, however, that liquid petrolatum might be even less irritant in man, and accordingly the menstruum was changed to liquid petrolatum. The fact that there are said to be ether drinkers in Ireland and France, who apparently suffer no more than alcoholics, made it seem additionally safe to try the mixture of the two for clinical work. Additional support was adduced from the fact that in many hospitals ether is

TABLE 1.—RESULTS OF EXPERIMENTS

Quinin and Urea Hydrochlorid

being applied as a local dressing without deleterious results. Finally, a 65 per cent. solution of ether in oil has been used in many thousands of cases of oil-ether colonic anesthesia without any sign of local irritation to rectum or colon, which has been proved by proctologic examination, as well as by the fact that no case of dysentery or bloody diarrhea has been observed.

Liquid petrolatum	4 fluidrams
Peppermint water	5 minims

CLINICAL DATA

The combinations given in Table 2 have been tried clinically. The mixtures containing paraldehyd were disagreeable to the taste and smell, the ether-oil very much less so; but the difficulty was soon overcome by following a suggestion by Major W. E. Lower. An ounce of port wine is placed in one glass and the analgesic in another glass. The patient takes a mouthful of wine, holds it for about thirty seconds, rinsing the mouth so as to get the aroma in the upper air passages and the taste well established, and then swallows the wine. The ether mixture is then taken and is followed *immediately* by the remainder of the wine. Several wines and liquors were tried, but the port wine was found to be the most satisfactory. One of us (J. T. G.) and several other physicians have taken this "Lower sandwich" and have found it not to be disagreeable and to produce analgesia. As will be seen from the case reports, numerous patients have been given it with excellent results. Only one patient has been nauseated, a man who was violently opposed to taking the wine. In contrast to that case, it was given to another man, who had repeated attacks of vomiting, immediately after an attack. His dressing was done without pain, and his vomiting ceased permanently. All the patients have been able to take food and water shortly afterward, and even in patients much exhausted by infection, there have been no deleterious after-effects. It was soon found that the paraldehyd served no useful purpose, and most of the dressings have been done with Formula 1. While it is well not to give the analgesic immediately after a meal, no especial preparation of the stomach is necessary.

TABLE 3.—REPORT OF OTHER DRESSINGS

Nature of Dressing	Time of Administration P. M.	Time of Dressing P. M.	Result	Pulse Before	Pulse After	Respiration Before	Respiration After	Pupils	After-Effects
Deep wounds of both legs; deep drains	2:32	2:50	Good	84	84	Normal		No effect	None
Large, excised, painful back wound	2:32	2:48	No pain	92	112	Normal		No effect	Nauseated and vomited
Stump, adherent dressings (3 times)	3:03	3:30	....	120	100	32	20	No effect	None
Through and through wound of leg, with drain	10:00	10:20	Good	*No change*		No change		No effect	None
Abscess of leg; multiple incision	10:00	10:20	Good	No change		No change		No effect	Patient cried out but remained flaccid; had little pain
Through and through drain; leg	11:00	11:15	Poor	No change		No change		No effect	Only half dose given; patient jumped and had pain
Stump dressing	11:15	11:30	Fair	90	99	No change		No effect	Patient cried out, but had less pain than when done before
Drains; foot		One-half fluidram had no effect whatever.							

Under the general direction of Major W. E. Lower, the following cases were dressed in No. 9 (Lakeside, U. S. A.) General Hospital, American and British Expeditionary Forces, by Lieutenants B. I. Harrison and W. R. Barney. All dressings were done without the removal of the patient from the ward.

REPORT OF CASES

Case 1.—A soldier, aged 36, who had received a gunshot wound of the right thigh, and had an infected, compound, comminuted fracture of the femur, had *found previous dressings very painful, and the splint could not be changed without general inhalation anesthesia.* He was given paraldehyd, 1 fluidram; ether, 3 fluidrams, and liquid petrolatum, 4 fluidrams. In fifteen minutes he fell into a light sleep. The wound was dressed, the splint removed, the through and *through wound irrigated with* ether, a gauze drain inserted down to the femur and a Thomas splint applied with extension. The patient talked during the dressing, felt practically no pain, and suffered no nausea or other unpleasant aftereffects. The dressing was repeated in a similar manner *every other day for four dressings, and in none of them was there pain or any alteration of pulse or respiration.*

Case 2.—A soldier, aged 28, who had a gunshot wound of the left thigh, with a compound comminuted fracture of the femur, was given the same mixture as in Case 1. He fell asleep after twelve minutes. The Thomas splint was removed and replaced, the gauze packing removed, the wound irrigated with ether, and another gauze pack reinserted. The patient groaned when the pack was reinserted, but after regaining complete consciousness he said that he had felt no pain during the dressing. Three subsequent dressings were done on alternate days with no nausea or other aftereffects nor alteration of pulse or respiration. The patient complained of the taste of the mixture, but said it was far to be preferred to the extreme pain of the dressings.

Case 3.—A soldier, aged 23, with gunshot wound of the left leg, a compound comminuted fracture of the tibia and fibula, a through and through infected wound, was given the same mixture. He fell asleep after fifteen minutes and slept for thirty minutes during which the dressings were done. The Thomas splint was repadded, the packing was removed and reinserted, and ether irrigation was done. Two dressings were done without ill after-effects.

Case 4.—A soldier, aged 39, who had sustained a gunshot wound of the left thigh, through and through, with a compound comminuted fracture of the head of the femur, had found all previous dressings extremely painful. He was given paraldehyd, 2 fluidrams; ether, 3 fluidrams, and liquid petrolatum, 3 fluidrams. The wound was cleansed, and the packing removed and reinserted. The patient groaned at one time, but had no later recollection of having had pain. The pulse increased from 108 to 110, and the respiration from 26 to 28. There was no nausea. Three subsequent dressings on alternate days were equally painless and without ill after-effects.

Case 5.—A soldier, aged 23, who had received a gunshot wound of the right leg, with an infected, compound comminuted fracture of the tibia, and had found dressings very painful, was given the same mixture as in Case 1. Dressing was done with much less pain than before. The pulse rose from 100 to 116, and respiration from 24 to 26. A few days later the dose was repeated, and the patient slept through the dressing. There were no ill after-effects.

Case 6.—A soldier, aged 27, with a gunshot wound of the thigh and a streptococcus infection, but no fracture, was given morphin tartrate,[1] ¼ grain; ether, 3 fluidrams; liquid petrolatum, 3 fluidrams, and paraldehyd, 2 fluidrams. Multiple superficial incisions were made for drainage with very slight pain, probably because of the dressing following too soon after administration of the mixture. The pulse rose from 110 to 120. The patient was vomiting before the mixture was given, but retained it and did not vomit afterward.

Several other dressings are briefly summarized in Table 3.

Following these experiments, one of us (J. T. G.) was ordered to a casualty clearing station. The following cases from the service of Captain D. C. Taylor, R. A. M. C., illustrate some of the possibilities of the method. Two almost parallel cases of penetrating wounds of the knee occurred, November 15.

Patient 1 was given the usual inhalation ether anesthesia with the Shipway apparatus. Patient 2 was given 1 ounce of 50 per cent. ether in liquid petrolatum. Thirty minutes later a supplementary 2 drams of chloroform were given by inhalation during the operation. The knee joint was opened, pieces of comminuted patella removed, and the joint was irrigated with saline solution and closed. Both patients rested quietly for one hour after operation. Patient 1 then complained and required a hypodermic injection of morphin for the control of restlessness and pain. About the same time Patient 2 awakened, drank some milk, and fell asleep again. Both patients slept until breakfast time. Patient 1 drank some tea, but refused other food. Patient 2 had tea, porridge, bread and butter. Neither patient vomited afterward, and both were evacuated to a base hospital in about four hours. Two other patients of Captain Taylor's were given each a double dose of the mixture (2 ounces of 50 per cent. ether in liquid petrolatum). Each required only a few additional drops of inhalation anesthesia. The resultant analgesia after operation was a little more prolonged than with inhalation anesthesia. One of these patients was ready for operation in ninety seconds and required 1 dram of chloroform given drop by drop to "carry on" an operation lasting thirty minutes.

The substitution of chloroform for paraldehyd has been found to make even a more satisfactory mixture than the preceding. The following formula has been used in approximately thirty cases: chloroform, from ½ to 1 fluidram; ether, 3½ fluidrams; liquid petrolatum, 3½ fluidrams. It is not recommended at the present time to exceed this. It is our opinion that the toxic effect of this small amount of chloroform can be disregarded in military surgery.

COMMENT

The physiology of "general analgesia" by oral administration has not been subjected to an exhaustive investigation, but certain important facts should be borne in mind by those who contemplate using the method outlined. The oil and ether mix perfectly and do not separate into layers. Baskerville has shown the rate of evaporation from minute to minute to be constant so as to form a straight oblique line when plotted out. This holds true with different percentages of ether in the oil, in all cases assuming a constant temperature and exposed surface. It is impossible, therefore, for the patient to get an overdose at one time and an insufficient amount at another time. The total amount is not absorbed at one time; if it were, the administration of 2 ounces of 50 per cent. ether in oil would produce complete anesthesia, as there would be liberated 1 ounce of ether. Only a light analgesia is obtained which, for operative procedures, must usually be supplemented in some way. Naturally, the surface for evaporation is greater in the stomach than is the case in the colonic method, and the absorption of ether is more rapid. The total amount that may be given with safety by this method has not yet been determined. It is considered advisable for the present to supplement the method either by local anesthesia or the administration of small amounts of anesthetic by inhalation. But it is important to remember that the patient is as safe by this method as if the ether were in a container outside the body. All anesthetics are analgesics, and before the danger zone is reached, the patient must become anesthetized; hence the patient in the analgesic stage is separated from the danger zone by the period of anesthesia. We consider analgesia by this method as safer than any method of anesthesia. If the anesthetist carries his patient to the "blear-eyed" snoring stage, he defeats the object for which this special method was devised, the object being to take advantage of the analgesic stage of any and all anesthetics used. If adopted, it would release from the routine of administration of anesthetics a certain number of physicians who now, in military hospitals, devote their entire time to that work.

CONCLUSIONS

It is felt that so far as one can do so in a preliminary communication of this sort, the following conclusions are justified:

1. General analgesia is safer than general anesthesia.
2. Fifty per cent. ether in liquid petrolatum or other bland oil is probably the safest general analgesic, has apparently no deleterious effect on the stomach, and is not followed by the nausea and vomiting that frequently accompany inhalation anesthesia. It may be given without unpleasant taste when "sandwiched" between mouthfuls of port wine.
3. The method is especially indicated during the dressing of painful wounds without taking the patient from his bed or ward, and when supplemented, can be employed for surgical operations.

Scientific Adulteration.—The amount of detail work required in making analyses of foods and drugs is increasing greatly. The manufacturing firms practicing the more skilful forms of adulteration often have experts who sophisticate scientifically. The finished product is so artfully adulterated that it is sometimes very difficult for the analyst to detect the fraud with certainty. Often it is necessary to make many analyses of products of known purity in order to determine the maximum limit of the variation of certain constituents. Again, an inspection of the materials at the source of production is needed. For instance, water is the cheapest and most readily available adulterant for use in sophisticating foodstuffs, and by the addition of a small per cent. in excess to a canned fruit or vegetable, an increased profit is assured and detection is often difficult.—Report of Food and Drug Department, Kentucky.

[1] Morphin tartrate is official in the British Pharmacopeia. Its action d dosage is the same as morphin sulphate.

SANITATION OF THE MARINE BARRACKS, QUANTICO, VA.

WITH SPECIAL REFERENCE TO THE METHODS OF CONSERVANCY EMPLOYED

W. L. MANN, Ph.B., A.M., M.D.
Passed Assistant Surgeon, U. S. Navy
QUANTICO, VA.

The medical officer, for obvious reasons, was the first of the military personnel to report on this station; about 200 laborers, arriving a few days before, had arranged for the pit system of latrines. On account of the potential menace of these fecal pits and the possibilities of their being dug up by pipe laying, road building, etc., they were ordered filled and the pail system of latrines susbtituted.

In a few days, Marines began to arrive, and in such numbers as to somewhat tax the sanitary service. On recommendations of the medical officer, by maintaining several hundred laborers working night and day, it was possible to complete the water carriage sewerage system in five weeks. The original estimate for this was from three to four months.

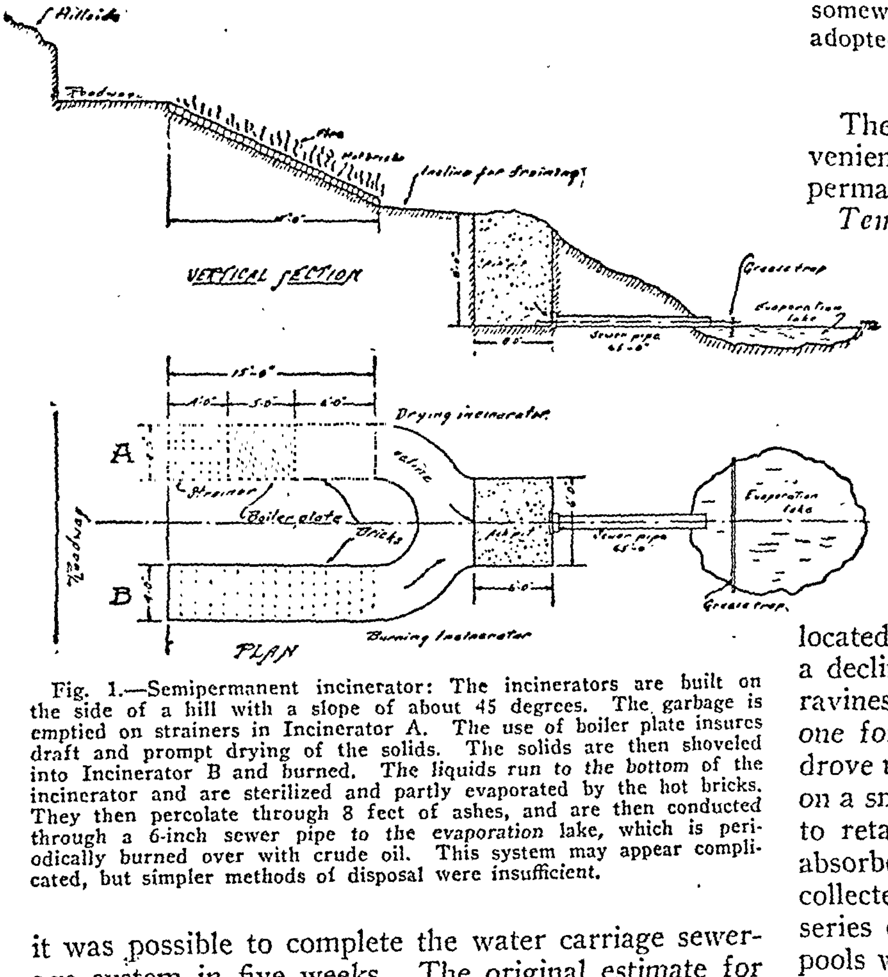

Fig. 1.—Semipermanent incinerator: The incinerators are built on the side of a hill with a slope of about 45 degrees. The garbage is emptied on strainers in Incinerator A. The use of boiler plate insures draft and prompt drying of the solids. The solids are then shoveled into Incinerator B and burned. The liquids run to the bottom of the incinerator and are sterilized and partly evaporated by the hot bricks. They then percolate through 8 feet of ashes, and are then conducted through a 6-inch sewer pipe to the evaporation lake, which is periodically burned over with crude oil. This system may appear complicated, but simpler methods of disposal were insufficient.

The camp site was found to be well situated, with the exception of marshes and swamps existing in proximity. This objection, however, was remediable; about 300 acres of swamps have since been drained. Quantico, according to the local physicians, had the reputation of being the "worst place on the Potomac for malaria."

The living quarters are of one story, are well ventilated and are built on the unit system, in accordance with recommendations of the Bureau of Medicine and Surgery. Their limited capacity (forty occupants) minimizes the possibility of a spread of infections.

The hospital for the station consists of six wards with a capacity of about 200 beds. This was built, equipped, organized, and occupied in the short period of forty-three days.

The post surgeon was appointed special health officer by the state board of health. This gave him the necessary authority to clean up the municipality and enforce such sanitary regulations as were deemed necessary.

The proximity to Washington enabled this station to secure the best of expert advice on subjects directly or indirectly connected with sanitation.

This station has had a maximum personnel of about 7,000 Marines, and it is estimated that about 15,000 have been stationed here at some time or another in the first six months of its occupation. During this period the following results may be noted:[1]

1. There has been no death from illness.
2. No epidemic tendency of the infectious diseases has occurred.
3. There has been an absence of any cases of serious illness, such as typhoid, meningitis and pneumonia.
4. The daily morbidity rate of malaria figures about 0.004 for the military personnel, although the malaria season was somewhat advanced before the completion of the measures adopted for mosquito control.

CONSERVANCY

The methods of conservancy employed may be conveniently divided into temporary, semipermanent and permanent procedures.

Temporary.—During the stress of the first few days, the sanitary laborers were instructed to remove and burn all excremental and garbage refuse. They were found later to have inaugurated a system of refuse incineration that was so simple, and worked so admirably, that no attempt at building regular incinerators was started until about six weeks later, when the removal of the place of incineration was necessitated by the proximity of the buildings under construction.

This method of garbage destruction consisted of a series of six parallel natural ravines located on the south side of a 15-foot bluff which had a declination of from 50 to 60 degrees. Two of the ravines were used each day, one for the kitchen and one for the excremental refuse. The garbage wagon drove up to the end of the bluff and dumped the refuse on a small pile of brushwood, which acted as a strainer to retain the solids, allowing the liquid to be partly absorbed while the excess drained downward and was collected immediately beneath the brushwood in a series of small pools 2 or 3 feet in diameter. These pools were increased in size and number as the necessity demanded. The fire was started below the lowest collection of liquid and was then gradually built upward. It was found that the lowest collection of liquid received the maximum heat, being nearest the fire, and tended to evaporate first. Consequently, after from one to two hours, it was possible to pile fuel upward gradually and to consume completely the dry and semicarbonized matter remaining at the upper portion of the ravine, leaving the soil hard, dry and sterile. At the close of each day these ravines were easily cleaned by raking the débris downward, using the tin cans and the ashes to fill up small swamps.

Subsequent information on the subject shows that this method of incineration is somewhat similar in principle to the inclined plane incinerators described by Lelean[2] in his "Sanitation in War." As the heat penetrates only 2 or 3 inches of the soil, a portion of the infected fluid may escape this sterilizing action of the heat. This, however, depends on the permeability of the soil (here it is clay), and the rapidity with which the fire is built upwards.

---

[1] This article was written, Dec. 1, 1917.

This mode of disposal has the following advantages:

1. Simplicity: One Virginia negro effectively and efficiently disposed of the excremental and garbage refuse of 2,000 persons.
2. Availability: Almost every terrain contains a sloping hillside or small embankment that may be utilized.
3. It requires a minimum amount of fuel, as the fire is below and the heated air rises and comes in direct contact with the liquid and semisolids.
4. The square area of surface of the fluid which is exposed to the heat is greatly increased, because of the earth's absorption, and this facilitates rapid evaporation.

Semipermanent.—It was at first possible to dispose of all liquid waste by evaporation; but shortly afterward, when supervision of the disposal for the municipality was assumed, this method became impracticable. Owing to the unusual amount of sullage water from the numerous small restaurants, the garbage at times contained 90 per cent. liquid. Soakage pit methods proved a failure on account of the low degree of permeability of the soil; and disposal in the river, because of the tides, proved equally unsatisfactory.

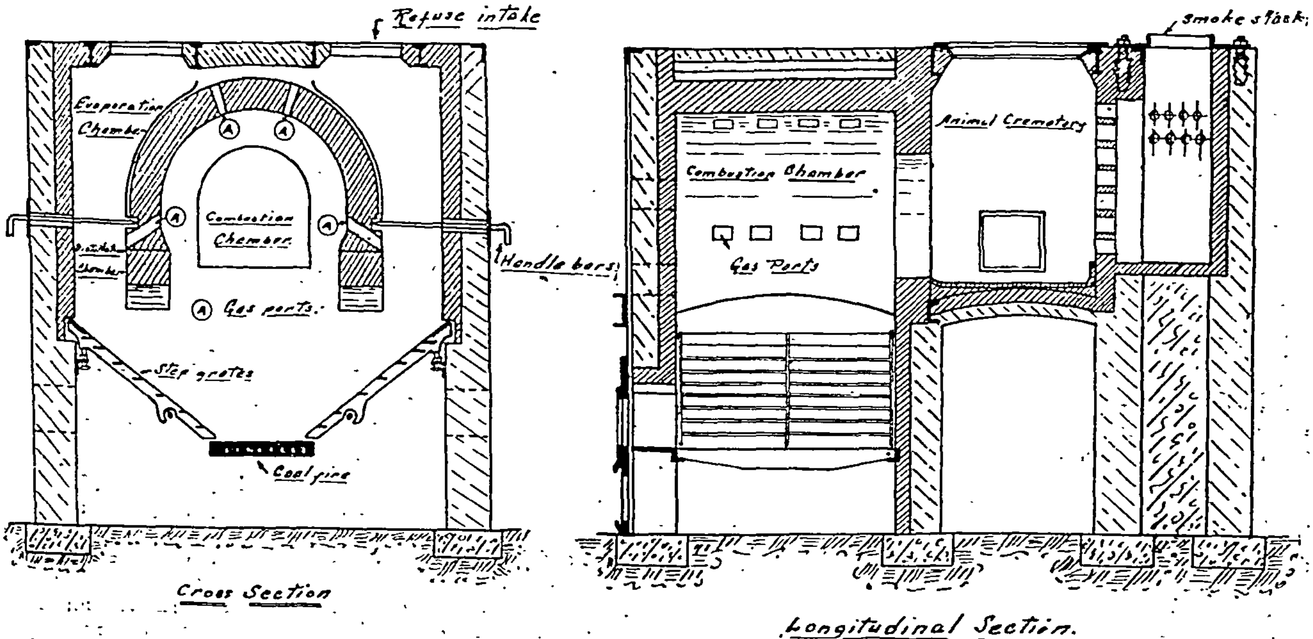

Fig. 2.—The garbage is placed in the refuse intake and dehydrated in the evaporation chamber. All vapors arising from this drying chamber are drawn by the chimney draft, through the gas ports, into the combustion chamber. The partly dried garbage is then charged into the distillation chamber by withdrawal of the handle bars. Here the heat is sufficient to distil the volatile hydrocarbons, which pass into the combustion chamber, through the gas ports, and are ignited. The fixed carbons remaining are burned on the step grates. The combination of the combustion space for both the solid matter and the volatiles insures the highest concentration of heat, and as all vapors and gases pass through this zone, the malodorous vapors are destroyed.

Figure 1 represents the final type of temporary incinerator evolved from the original idea of hillside incineration. Incidentally it might be stated that many varieties of field incinerators were constructed either for demonstration or for experimental purposes.

Permanent Arrangements.—Each kitchen has its individual incinerator, a type slightly modified from those used by the Army. This method obviates collection, storage and transportation of the garbage, by permitting immediate destruction in situ. Theoretically, the idea is excellent, but it has been our experience that these incinerators are not economical in fuel and that their efficiency varies and is dependent, in a large measure, on the personal equation of their operators.

Recently a large central waste destructor has been built. This requires a minimum amount of fuel, and the burning garbage automatically furnishes sufficient hot water for cleaning the cans. The "two can system" allows the truck on each trip to replace the used cans with cleaned receptacles.

The application of a well known principle causes the operation of this incinerator to be nonodorous. It is a device patented by the corporation selling it. Briefly, the green garbage is charged through hoppers into the "evaporation chamber." Here the garbage is partly dehydrated, and by removal of the handle bars the garbage is then thrown into the "distillation chamber." The heat here is sufficient to drive off the volatile hydrocarbons, which gases are then drawn through gas ports into the "combustion chamber," the temperature of which is sufficiently elevated to produce ignition of these. The solid fuels or fixed carbons remaining are then raked on the coal fire and there completely incinerated.

At present the water carriage sewerage system empties into the Potomac River. Plans are under way for the construction of a septic tank, with treatment of the effluent preliminary to the discharge into the river.

Accident Insurance and Ptomain Poisoning.—Death from ptomain poison contained in mushrooms supposed to be edible, and eaten by the insured without negligence, is held within a policy insuring against death by accidental means not resulting from or contributed to, directly or indirectly, wholly or partially, by disease, in the Indiana case of *United States Casualty Co.* v. *Griffis,* L. R. A. 1917 F, 481.

CLINICAL AND PATHOLOGIC NOTES ON TRENCH NEPHRITIS

W. H. TYTLER AND J. A. RYLE

(Abstract from the Quarterly Journal of Medicine, London, 1918, **11**, *p. 112)*

These British officers describe the clinical features in 150 cases of trench nephritis observed during the early stages in a casualty clearing station. They also record the results of pathologic examination of cases which terminated fatally within the first three weeks of the disease. They were all cases presenting constitutional symptoms as well as albuminuria, no cases being included of the prevalent albuminuria without indisposition, and none of the so-called "lower tract" cases. All the patients were employed in the forward area and the great majority actually in the trenches. There was commonly no history of any predisposing illness, nor were there any concurrent epidemics, such as scarlet fever or tonsillitis, which could be considered to bear on the etiology of the disease. The seasonal incidence showed a marked increase during the winter months.

SYMPTOMATOLOGY

The cases were observed during the early part of 1916, and the entire following winter. The history was usually of an onset from two or three weeks previous to admission. The almost constant complaint was of shortness of breath on exertion, while swelling of the extremities and face was also frequently noted. A history of cough and of a general feeling of unfitness was common. The history of onset did not suggest an acute febrile or septicemia attack. On admission, and throughout the early course of the disease, the most striking symptoms were pallor, edema and dyspnea. Of the more severe cases, comprising between 20 and 25 per cent. of the whole number observed, the following description is given:

> "The patients were pale and puffy, with edema of the eyelids, face, feet and hands, and, after a short time in bed, of the back and flanks, which might show deep creases due to the pressure of folds in the bedclothes. The abdomen, on palpation, was full and tense. The spleen, though often enlarged postmortem, was never palpable during life. The respirations were short and rapid, and the dyspnea increased on the slightest exertion. There was impaired resonance and air entry at the bases, with or without moist sounds. The worst cases showed cyanosis of the lips and ears. Nearly all required a bedrest to give them relief, while continuous administration of oxygen was sometimes necessary. Except as a terminal event, expectoration was not commonly profuse. One case had a large bilateral pleural effusion, but in the remainder of the series pleural effusion was uncommon, and when present not of large amount."

The bronchitis, as a complication of the nephritis, was usually present on admission, "and was undoubtedly a prominent cause of the severe respiratory symptoms." The dyspnea was frequently urgent and distressingly obvious. So predominant were the respiratory signs that, until the condition became more generally recognized in the field ambulances, cases were not commonly sent down with a diagnosis of acute bronchitis or of pneumonia. From clinical evidence the authors consider the dyspnea "to be primarily due to pulmonary edema, and this view was substantiated by the necropsy findings. Bronchitis was undoubtedly a great contributory factor, and swelling of the abdomen and of the tissues of the abdominal wall probably played a part." A striking resemblance was frequently noted between the respiratory symptoms in trench nephritis and those seen in cases of gas poisoning.

The pulse, in nearly all cases, was full and bounding, and the blood pressure was generally above 140 mm. of mercury. One patient showed subconjunctival hemorrhages. Pyrexia was not the rule save in relation to the bronchitis. A small group of cases, however, without apparent bronchitis, showed temperatures ranging from 100 to 104 F., during the first week of the disease. Another small group of cases showed the respiratory picture described above, with the addition of prolonged expiration and the general symptoms of severe asthma, but with complete absence of external edema. The presence of albumin and casts in the urine, and the relatively small amount of expectoration, served to distinguish this group from the cases of simple capillary bronchitis which were so numerous during the winter. In spite of the anasarca and the pulmonary edema the patients usually passed a quantity of urine not much below the normal amount. None of the cases with respiratory symptoms and edema showed evidence of uremia.

In the fatal cases death usually occurred during the second week. In such cases the terminal picture showed increased cyanosis, and very severe dyspnea with profuse frothy expectoration. Death in all the fatal cases was apparently due to respiratory failure.

PROGNOSIS

The mortality among cases of nephritis admitted to this casualty clearing station during the winter of 1916-1917 was 4 per cent. All of these fatal cases were of the respiratory type, and in all but one there was associated bronchitis. "The immediate prognosis, then, in the absence of this very common complication, may be said to be good in the dyspneic form of the disease. The uremic type, from the experience of those who have seen more of it, shows a higher mortality rate."

TREATMENT

The authors emphasize that "the first essential in successful treatment is early diagnosis. Cases which had been first recognized late in the disease were in general slower in their reaction to treatment." Warmth and rest in bed with good nursing and the administration of saline purgatives, produced a rapid change in the condition of all cases of moderate severity. Postural treatment of the dyspnea, and oxygen when necessary—given preferably by the continuous intranasal method—gave much relief. Hot packs were often beneficial, but seemed to be definitely contraindicated in cases with pyrexia or severe bronchitis. The diet was customarily fluid, sometimes with the addition of light farinaceous foods. "So far as possible patients were not evacuated until the symptoms had largely disappeared. In uremic cases bleeding and lumbar puncture may give relief, particularly the former."

URINE EXAMINATION

The urine nearly always showed a large amount of albumin on admission, the amount being roughly proportional to the severity of the symptoms. Specific gravity varied between 1.012 and 1.018, with an average of 1.015. Of the entire series of cases only about 2 per cent. showed macroscopic hematuria. Microscopically, the centrifugalized urine showed numerous tube casts, red blood cells and leukocytes. The number of casts, however, was usually smaller than in severe acute nephritis as seen in civil life.

THE BLOOD

Urea in the blood varied from 0.05 to 0.15 per cent., with an average of 0.08 per cent. The amount did not seem to bear any constant relation to the amount of urea in the urine. Leukocytes in a small series of cases were not definitely increased, the usual figure being between 8,000 and 10,000. Higher counts were not observed save with severe bronchitis.

PATHOLOGY

The morbid anatomy in trench nephritis is based on a series of twenty-five necropsies. The most constant gross changes observed were those seen in the lungs and spleen, consisting, briefly, "in an extensive pulmonary edema, often of rather characteristic nature and usually accompanied by a purulent bronchitis, and in the presence of characteristic hemorrhages throughout the spleen. The kidneys constantly showed to the naked eye only the most slight and indefinite changes. "It was seldom that one could attempt even a guess at the nature of the disease from the gross examination of the kidneys alone." They were seldom enlarged, and the only change suggesting disease was a slight pallor and opacity of the cortical tissue. The cortex was seldom swollen or wider than natural. A few of the kidneys showed some congestion so that the cortical vessels stood out as red streaks against a pale background. In some cases swelling of the glomeruli, causing them to stand out from the cut surface like minute glistening drops, was observed. This change, however, was not constant. Hemorrhagic lesions were not infrequently seen elsewhere than in the spleen. Several cases showed petechial hemorrhages in the renal pelves. Two cases showed numerous subepicardial, and one case numerous subpleural petechiae. Two cases showed large cerebral hemorrhage, one central and one superficial. The heart was often considerably dilated when the lung involvement was extreme, and such cases showed venous engorgement of the abdominal viscera. In most cases congested lymph nodes were found at the roots of the lungs, and often in the mesentery. The brain in some cases showed moderate subarachnoid edema.

ETIOLOGY

Bacteriologic examination was carried out on material from sixty cases taken during life, and from sixteen of the series of twenty-five necropsies. Blood cultures were made on a series of ten cases, all in the early stages of the disease, and all showing pyrexia. One case yielded an organism which was apparently a pneumococcus, growing in short chains with definite capsules. "The presence of this organism in the blood was probably secondary to a pneumonic process in the lung." The cultures in the remaining nine cases remained sterile. In a series of forty cases cultures were made from the urine. In twenty-four of the forty cases the urine yielded streptococci of the enterococcus or fecal type. These organisms produced a luxuriant, confluent, often opaque growth on serum free agar—sometimes simulating a staphylococcus—and on blood agar produced colonies up to 1 mm. in diameter, rather opaque by transmitted light, with a narrow green halo, and reflected light often whitish, the halo then appearing as a blackish background to the colony. Under the microscope they showed short chains of often elongated cocci. In most of the cases hemolytic streptococci were present as well.

The urine from a series of fifty control cases was then examined. These embraced many conditions, the diagnoses including diarrhea, trench fever, pneumonia, cerebrospinal fever, scarlet fever, trench feet and several others. In only five of these cases were streptococci isolated which produced a green color on blood agar. Most of the control urines yielded hemolytic streptococci. In twelve cases cultures were made from the throat. The cultures from ten of these cases yielded streptococci producing fine dryish colonies on blood agar, with a pronounced green halo. Several cases also yielded pneumococci. In no case was an organism of the enterococcus type recovered. In sixteen cases cultures were made at necropsy from heart blood, lungs, spleen and kidneys. In nine cases streptococci were isolated from the lungs, in six cases from the spleen, and in two cases from the kidney. Cultures from heart blood remained sterile in every case. The streptococci from the lung were all of the type described as recovered from the throat cultures, and were never of the enterococcus type. The organisms isolated from the spleen and kidney, on the contrary, were in general similar to those found in the urine of nephritis cases, and may be considered as enterococci. In one of the two cases in which an organism was isolated from the kidney a similar streptococcus was recovered from the spleen also, and in this case streptococci could be demonstrated in the tissues. During the season at which influenza was prevalent influenza bacilli were isolated from the lungs of two cases and from the kidney of a third. Broth cultures of three organisms from the urine, three from the throat, and one from the spleen were injected subcutaneously into mice, the dose being 1 c.c. All the animals died in from three to five days, but in no instance could the streptococci be recovered from the blood or organs.

SUMMARY

In the early stages of the attack general edema, dyspnea, albuminuria with casts, red corpuscles and leukocytes in the urine, which is not, or but very little, reduced in amount, were the principal features. In the fatal cases death may be caused by respiratory failure from edema of the lungs, usually associated with severe bronchitis, the latter being regarded as secondary. The characteristic changes were found in the lungs, the spleen and the kidney, in all of which capillary thromboses were present, most marked, however, in the lungs and in the kidney associated with acute glomerulitis. The most marked changes were found in the lung. There was a diffuse edema with some fibrinous and cellular exudate, the condition being really one of pneumonitis rather than edema in the usual sense, and associated therewith was a bronchitis which the authors regard as secondary. Bacteria were not found in the lungs except in the bronchi, in which were streptococci of the mouth type. Beside the thromboses in the spleen there were many small hemorrhages, and hemorrhages were also found in the serous membranes and in two cases in the brain. The changes in the kidney were less marked than expected from the symptoms, being principally inflammatory changes in the glomeruli. In nearly two thirds of the cases, streptococci of the intestinal type were found in the urine. It is apparent, both from a clinical and anatomic point of view that the changes in the lungs are the predominating ones, and there is good reason to doubt that conditions in the kidneys would explain the phenomena of trench nephritis—a view which should have an important bearing on the direction of future investigations of these conditions. It is of interest that the changes in the lungs being of an inflammatory nature, but not associated with bacteria, apparently favor the view that inhalation of gas and other fumes may play a positive rôle in trench nephritis. The authors emphasize, however, that the disease may develop in places where such inhalation is excluded. While the condition in the lungs may be due in part to the general edema, features are present which indicate an inflammatory process, the origin of which remains unexplained.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

DICHLORAMINE-T.— Paratoluenesulphonedichloramide. —$CH_3.C_6H_4.SO_2NCl_2$.—The dichloramide of paratoluenesulphonic acid, $CH_3.C_6H_4.SO_2OH$.

Actions, Uses, Dosage, Physical and Chemical Properties.—See New and Nonofficial Remedies, 1918, p. 157.

Dichloramine-T, Monsanto.—A brand of dichloramine-T complying with the N. N. R. standards.

Manufactured by the Monsanto Chemical Works, St. Louis. No U. S. patent or trademark.

Manufacture of Organic Chemicals.—In *Science*, March 8, 1918, Dr. Roger Adams describes the activities of the laboratories of the University of Illinois in making rare and much needed chemical products for research and teaching work for the laboratories of the United States, the supply of which was formerly obtained largely from abroad. Eight different chemicals in amounts valued at $5,000 were made, and more than thirty laboratories and distributing houses were supplied. The work has expanded since so that about 120 different products have been supplied outside the laboratory, valued at about $9,000, the products being distributed in amounts of a few grams up to pounds. Among the different chemicals synthesized which were in demand in the laboratories are dimethyl glyoxime, nitroso beta naphthol, cupferron, nitron and ninhydrin, besides many others. They have all been tested in comparison with a well known standard product, and in all instances have been found as good and in many instances much better.

THE MILLING PROCESS AND BERIBERI IN WAR TIME

Beriberi began to become a disease of prominence in the Far East when polished or highly milled rice began to take the place of the natural brown rice. The difference between these two forms of the cereal lies in the fact that modern milling removes the embryo and a considerable part of the pericarp of the husked grain. Since the rice bran or rice polishings representing the removed portions contain substances essential to nutrition, a deficiency manifested itself through the use of the polished rice whenever it constituted a very considerable part of the ration. To the indispensable component of the polishings the name "vitamin" has been given. Beriberi has been the most characteristic instance of so-called "deficiency disease," because the origin of the dietary deficiency in an inadequate diet is now clearly understood, and because its most prominent symptoms can be both reproduced experimentally by an exclusive diet of polished rice and cured by administration of suitable sources of vitamins. On the basis of this knowledge, beriberi induced by the undue use of polished rice has been averted in many quarters in the East and much suffering has been prevented by the judicious selection of the diet, as for example in parts of the Philippines. Indeed, it might be supposed that except for the uncontrollable habits of certain primitive peoples, the danger of the occurrence of beriberi on a large scale is practically a matter of the past in all countries and climates.

The history of the present war has shown, however, that this is by no means the case. Beriberi was reported to occur among the British forces in the Dardanelles and Mesopotamia during the autumn and winter of 1915. Owing to the exigencies of the military situation, many persons in those regions subsisted for considerable periods mainly on canned meats, jam and white bread, or crackers baked principally from white flour. This has raised anew the question of the distribution of vitamins in the various parts of the wheat with a view to ascertaining whether the parts of this cereal removed in milling white flour are peculiarly valuable as sources of antineuritic vitamin.

During the "roller" milling of wheat, the brittle pericarp is broken up by the rollers into bran, while the embryo, being soft and oily, is squeezed out flat. In the sieving and fanning of subsequent operations, the bran and embryo are separated so that each may be obtained as such and examined. In the case of rice milling, however, the polishings contain a mixture of pericarp and embryo, since these are not so easily separated by the mechanical processes in technological use. The embryo of rice can, however, be removed alone by more laborious methods. In an elaborate study conducted at the Lister Institute for Preventive Medicine in London, Chick and Hume[1] have demonstrated by means of curative experiments on polyneuritic pigeons that in both the rice and wheat grain, the antineuritic vitamin is concentrated mainly in the germ or embryo; it is also present to a less degree in the bran (pericarp and aleurone layer), probably in the aleurone layer. In case of maize grain, the embryo also possesses marked antineuritic properties. Here the scutellum can be separated from the "plantlet" and separately investigated. Both these constituents of the embryo were found to contain antineuritic vitamin. These conclusions are by no means new in all their details; but what these investigators found cannot be too strongly emphasized, namely, that the more important location of the antiberiberi vitamin is in the embryo or germ and not the pericarp of the grain.

Ordinary white flour consists of the wheat endosperm left after removal of the aleurone layer in the milling process. Such flour is deficient in the antineuritic vitamin, and Chick and Hume remind us that the endosperm, if used as an exclusive diet, will induce polyneuritis in pigeons (or beriberi in man) in a manner identical with polished rice. Several years ago Little[2] reported in The Journal that in Newfoundland and Labrador, where in midwinter and spring many persons are obliged to subsist largely on bread, beriberi frequently occurs. At the present time the bread is made from fine wheat flour; in the memory of the older inhabitants, when the bread was made from "brown" flour, the disease was unknown. In 1910 the following interesting event took place: A ship laden with whole-wheat flour ran ashore, and a considerable proportion of her cargo was removed in order to lighten her, and later was consumed by the adjacent population. There was no case of beriberi in that region for a year following this occurrence. Taken in connection with the outbreaks of beriberi that have been reported in connection with British troops living on restricted rations, these comparatively recent experiences indicate that special precautions are called for when the diet is liable to consist largely of foods deficient in vitamins.

[2] Little, J. M.: Beriberi Caused by Fine White Flour, The Journal A. M. A., June 29, 1912, p. 2029.

The British investigators have reached the conclusion, therefore, that for the prevention of beriberi it is in the highest degree desirable that the germ (embryo) and the bran of wheat should not be excluded from the flour destined for manufacture of bread and biscuit for troops on active service. This is the more necessary when the troops are separated from fresh food supplies, and the rest of the ration consists largely of tinned foods.

We are aware that technical difficulties arise in the packing and transporting of whole-meal or germ-containing flour. It seems likely that expert advice can overcome this; at any rate the problem involved deserves most careful study from those competent in this field. Baked products like crackers or biscuits can doubtless be shipped without encountering the difficulties presented by the flour itself. It must not be assumed from what has been stated that wheat germ is the only available source of antineuritic vitamin, or that the dangers just emphasized apply with equal force to all individuals in the population. Where liberal variety in diet is possible, the chance of deficiency is greatly reduced; but there are plenty of instances in which extremes of climate, temporary separation from a diversity of fresh food supplies, or the exigencies of active service on long campaigns or during siege have brought untoward consequences. We must learn to avert these as far as possible. As most cases of human beriberi have in the past been attributable to a defect in the character of the cereal employed in the ration, and as the germ or embryo of the grain is the principal source of the antineuritic vitamin, the suggestion of an alteration in the kind of flour supplied where deficiencies are most likely to arise seems well worthy of serious consideration.

Chick and Hume[3] have recorded several impressive instances which further illustrate that deficiencies can occur as the result of milling innovations. They state that beriberi was rare on Norwegian ships before 1894, after which date it became much more frequent. This frequency coincided with an alteration of diet which was made compulsory in that year in response to a popular demand for an "amelioration" of the conditions of life in the Norwegian mercantile marine. Previously the sailors on long voyages used biscuit made from rye flour; subsequently the masters of ships were obliged to supply bread baked from white wheaten flour, or a mixture of wheat and rye flour. It is an interesting corollary to note that in the milling of rye flour there is no separation of the germ. Again, it is pointed out as very significant in connection with the siege of Kut-al-Amara that beriberi should have broken out among the British troops while on their normal ration of white wheaten flour, and should have cleared up when they were obliged to share in the more coarsely milled (and doubtless germ-containing) grain of their Indian fellow-soldiers.

THE RISING COST OF MILK

Until recently, the problems of the milk supply were considered almost exclusively from the sanitary side. That the milk of different breeds of cattle may have unlike chemical composition, particularly with respect to the content of fat, has of course not entirely failed of recognition; but, after all, discussion has centered preeminently about those questions that relate to the presence and entrance of bacteria into the milk and to the methods of maintaining a high standard of milk hygiene. Confronted suddenly with enormously increased costs in many of the common foods, among which milk belongs, consumers are asking whether they are justified in paying the price now demanded. The public is assured by our experts in nutrition that it would be a misfortune to have the supply and the purchase of milk decreased in this country, where its use is well within what are considered optimal limits. The Journal has repeatedly subscribed to the same sentiment. Admitting the general proposition of the prime necessity for milk, the consumer properly asks whether the existing conditions in the milk market are defensible.

In the past, we have attempted occasional critical discussions of various factors concerned in the production of milk. Recently the Agricultural Experiment Station of the University of Wisconsin, at Madison, has collated the newest facts regarding the partition of the expenditures ending in the sale of milk to the consumer.[1] It appears that, under Wisconsin conditions at least, the farmer is getting something over half of the money that the consumer pays for milk. The farmer's share might be increased if he could avoid producing a surplus at certain seasons of the year, or if he could himself take care of this surplus without throwing it on the milk market. Transportation costs about 8 per cent., handling at the milk plants of the distributors involves an outlay of a further 18 per cent. for bottling, pasteurizing and other items of preparation, and the delivery system adds the final quarter of the total expenditure.

In considering the possibility of economy, the expense of distribution appears to be the only item that offers any prospect of reduction under present conditions. The Wisconsin report points out that with our present competitive system of distributing milk, there is an unnecessarily large amount of duplication. Not only are there often more men engaged in the business of delivering milk than are necessary, but each has more machinery and general equipment than are necessary in handling his business; that is, each could usually handle much more business without a great increase in his fixed investment. In almost any town one may frequently see three or four delivery wagons on the same street, at the same time, literally traveling in each other's tracks. Various remedies have been proposed, such as cooperative distribution, municipal monopoly, a private monopoly publicly controlled to place service above profits and allow a normal return on a reasonable investment of capital, or a method of marketing through stores that already have a delivery system for other commodities. Such economies would reduce the total cost of milk a little more than one eighth. If we may take Wisconsin as a typical state, it appears that the per capita consumption is less than 0.6 pint per day. In consideration of all the circumstances, possibly we should be content to accept current prices as reasonable under existing conditions. While milk prices have increased rapidly of late, they have not risen so rapidly or so much as have prices of other foods.

[1] Hibbard, B. H., and Erdmann, H. E.: Marketing Wisconsin Milk, Bull. 285, Wisconsin Agric. Expt. Station, December, 1917.

Grades of milk now found on the market are not such as are most helpful to the consumer in aiding him to select the class of milk he wishes to buy. Were such grades established, milk would sell more nearly on a quality basis. Since it is difficult for most consumers to recognize quality in milk, unrestricted competition in its production and distribution tends to lower quality. If we cannot lower the price of milk, we can at any rate try to get a good return for the expenditure.

PULMONARY VENTILATION IN TRAUMA AND SHOCK

The contributors to The Journal have lately given evidence of the intense interest which the misfortunes of war have awakened anew in the ever present subject of shock. In the series of articles on the nature and treatment of wound shock and allied conditions,[1] by observers who had exceptional opportunities to observe the patients in the early stages of injury, the occurrence of what has sometimes been termed acidosis has been reported as a characteristic sequence to trauma. Emphasis has been placed on the lowering of the alkali reserve of the blood, on the fact that under anesthesia and operation a further lowering occurs, and on the corollary that the intravenous infusion of alkaline solutions seems to provoke a prompt, beneficial response.

Recently attention was directed to Yandell Henderson's experiments showing that the factor of the alkali reserve of the blood is undoubtedly affected by altered breathing.[2] In researches with Haggard,[3] he has demonstrated anew that excessive pulmonary ventilation by means of artificial respiration induces not only a lowering of the carbon dioxid content, but also of the carbon dioxid capacity of the blood. Arterial pressure also falls, and death from circulatory failure may follow. If the artificial respiration, instead of being made with fresh air, is carried on by continual reinjection mainly of expired air, so that the carbon dioxid content of the blood is not reduced, the carbon dioxid capacity and arterial pressure do not fall and the other ill effects also fail to appear. Now the pain that the wounded feel is commonly attended by excessive breathing. The question, therefore, naturally arises whether abnormally extensive pulmonary ventilation induced by pain, pain hyperpnea, can account for the diminished alkali reserve reported for the shocked victims of the battlefield, or whether the trauma per se plays a part. Henderson and Haggard,[4] working at the Yale Medical School physiologic laboratories, have reached the conclusion that apart from overventilation of the lungs, trauma does not cause a lowering of the carbon dioxid capacity (alkali reserve) of the blood, even when by general traumatization and cooling of the abdominal viscera and consequent stagnation of the blood in the injured parts, failure of the circulation and death are induced. If, on the other hand, no measures are taken to prevent excessive pulmonary ventilation, the overbreathing induced by localized manipulation of the stomach, while the rest of the viscera are protected, causes lowering of the carbon dioxid content and carbon dioxid capacity of the blood and also of arterial pressure. If the lowering of the carbon dioxid capacity is pushed beyond the apparently critical level, between 33 and 36 per cent. by volume, the disturbance of the vital equilibrium results fatally. The same duration and degree of localized manipulation administered while the subject is inhaling 6 or 7 per cent. of carbon dioxid does not cause any marked lowering of the carbon dioxid capacity, arterial pressure, or general vitality. Below the critical level for the carbon dioxid capacity, treatment by the administration of from 7 to 10 per cent. of carbon dioxid in the air breathed does not cause restoration of carbon dioxid capacity or arterial pressure.

It is not unlikely, according to Henderson and Haggard, that when a very low level of carbon dioxid capacity is reached, a true acidosis due to tissue asphyxia and production of abnormal acid metabolic products may supervene. But if the maintenance of a proper alkali reserve or carbon dioxid capacity of the blood is dependent on a suitable not too low content of carbon dioxid in the blood, the long suggested plan of administering carbon dioxid in certain types of shock, as well as in the dangers of ether anesthesia, cannot be passed by without thoughtful consideration. There are indications already available that the proposed procedure will be given an opportunity to demonstrate its possibilities in the present crisis.

SUGAR IN WAR TIME

During recent months, many physicians have been asked regarding the possible effects of the various newly imposed or proposed dietary restrictions or innovations on the health of the individual. Despite the widespread acquiesence of our population in the dictates of the national and state food administrations, there is not unnaturally a frequent final appeal to the members of the medical profession for approval of such changes as have been proposed in the interest of the movement to help win the war. Among other plans for conservation, a reduction in the use of sugar has been urgently requested and, indeed, made inevitable at times when local shortage has curtailed the available supply so that the customary quota is not forthcoming. A summary compiled for the War Emergency Food Survey Section of the Bureau of Markets[1] furnishes facts that will enable us to draw conclusions more definite than those permitted by vague generalizations from intangible sources. The most pertinent information is that respecting the actual use of sugar in the United States in recent years. The amount consumed in 1917 was approximately 9,100,000,000 pounds, or 88.3 pounds per capita. In 1916 it amounted to 8,300,000,000, or 84.7 pounds per capita. It is thus apparent that if these statistics are correct there has been some increase in the consumption of sugar.

Eighty-eight pounds of sugar per capita used each year represent about 110 gm. (nearly 4 ounces) per day for every man, woman and child in this country. Expressed in terms of food fuel units this is equivalent to 440 calories, a not inconsiderable portion of the daily energy needs of an adult man. The sugar of the daily diet consumed in the measure indicated by the government statistics would furnish one seventh of the food fuel where 3,000 calories are required, and even a larger proportion where the daily energy requirement is put on a lower basis. Four ounces of sugar, as the accusation now stands, is the calorific equivalent of two thirds of a quart of good milk or of eight slices of bread approximating one third of a pound.

When it is recalled that this great per capita consumption of sugar is largely a phenomenon of recent years and the result of the development of an industry whereby the price of the product has been lowered, the necessity for the inclusion of this carbohydrate up to one seventh or even one fifth of the daily energy requirement in the diet will obviously be questioned. Sugar is primarily used for its flavor rather than its fuel value. One American student of nutrition has even gone so far as to question the physiologic wisdom of the modern increased consumption of sugar. Thus Sherman[2] writes:

> The cheapening of a staple article of food, which is almost universally popular and which, like the refined sugar of commerce, is of uniform and well-known composition and practically free from danger of adulteration or harmful deterioration, would be a source of great satisfaction but for the fact that refined sugar constitutes an extreme case of a one-sided food, its sole nutritive function being to serve as fuel so that, as the energy requirement of the body is met to a larger and larger extent by the consumption of refined sugar there is a constantly increasing danger of unbalancing the diet and making it deficient in some of the substances which are needed for the building and repair of body tissue and for the regulation of physiological processes.

From a practical standpoint it is pointed out in a government bulletin[3] that in the American cuisine sugar is used with too many kinds of food, with a consequent loss of variety and piquancy of flavor in the different dishes. The nutty flavor of grains and the natural taste of mild fruits are very often concealed by the addition of large quantities of sugar.

Sugar is well utilized in the human organism; from the standpoint of cost its food value is very high, and its popularity need not be debated. But there is no consideration of nutrition that seriously demands so large an inclusion of sugar in the diet or forbids considerable reduction in its use, especially when the best interests of the civilized world demand it.

Zoology and the War.—It is often said that this war is a scientific war and it is true both in its destructive aspects and in its safeguarding and protecting features. It is equally true that when *all* is said as to guns and explosives and poisonous gases, the last word lies with the man power of the belligerents. And it is here that zoology's great service is rendered. It is purely biological studies that have made possible the assembling of great numbers of men without disease slaying far more than fall before the guns of the enemy. The surgery which restores 90 per cent. of the wounded would be impossible without the knowledge reached by decades of parasitologic research. Our knowledge of sanitation and the prevention of infectious disease has doubtless saved many more combatants and noncombatants than have been slain in all the battles. It is not only Serbia which has been saved from typhus. Without our knowledge of the transmission of this disease, and the preventive measures thus made possible, all the belligerent nations would have been decimated by this scourge. Typhoid fever, cholera, bubonic plague, smallpox, would each have taken similar toll. For every dozen lives lost from battle, hundreds would have been destroyed by infectious diseases which we are now able to hold in check.—Prof. Maynard M. Metcalf in *Scientific Monthly.*

Current Comment

THE YIELD OF FOOD PER ACRE IN THE UNITED STATES

To many well educated persons it has become comparatively easy nowadays to think of food in terms of its energy value, and to express nutritive needs by calories. We owe this fact largely to the rapid popularizing of the science of nutrition, a movement largely fostered in this country by the efforts of the late Professor Atwater and his various associates, and probably not equally by any other nation in the world. Any one who knows the needs of the individual can estimate the requirement of the nation, so far as the problem is one of mathematics. Today we are face to face with precisely such problems. Food has become associated with patriotism, and there is nothing to be ashamed of in linking these words together. In their story of the food problem, Kellogg and Taylor have remarked:

> It is a time of rare and glorious opportunity; a time in which prosaic business and industry may be lifted up to the high plane of national service. And it is being so conceived in many quarters. The editor of a miller's journal puts it well for his miller and baker readers when he says: "He who grinds a barrel of flour or makes a loaf of bread to the glory and good of the nation, forgetful of self, performs his duty in a spirit of devotion equal in its way to that of him who goes forth to actual battle."

In the face of a world shortage of food there is something more than scientific inquisitiveness, therefore, in attempting to ascertain the comparative productiveness of our land in terms not usually employed. Many of our readers are conversant with the acreage crop of many foods. They think of a yield of 35 bushels of corn or oats per acre in contrast with 20 bushels of wheat on the one hand and 100 bushels of potatoes on the other. But the United States Department of Agriculture[1] has recently attempted to furnish an acre-for-acre comparison of different crops and animal products in terms of nutrients for man. At the head of the list of crops commonly grown in this country stands corn, a 35-bushel crop of this cereal producing 150 pounds of protein and more than 3,000,000 units of energy. This fact in itself speaks for the importance of encouraging the use of corn by improved milling and culinary procedures. Next in order stand sweet potatoes and Irish potatoes, with calories-per-acre values of 2,000,000 or more. Corn is ahead of all other crops except navy beans and soy beans in tissue-building material. In the latter element soy beans far outclass all other crops, showing nearly twice as much protein per acre as navy beans, which rank second in this regard. The statistics show that the dairy cow is the most efficient of farm animals in the production of human food (milk), and that the hog is the most efficient in the conversion of grain into meat, producing five times as much per acre of crops as does any other animal. The calories-yield per acre, rese when suitable crops are converted into pork, is estimated at nearly 700,000 calories, in contrast with 130,000 calories similarly furnished by beef. Where milk is produced, however, the record of the hog is eclipsed.

THE MEASURE OF ACIDOSIS

A comparatively simple and seemingly practical method of ascertaining the existence of a condition of acidosis in the organism, and the degree to which it has developed, consists in what has been fancifully termed "titrating the body." This amounts to a determination of the quantity of an alkali—sodium bicarbonate—that is required to change the reaction of the urine so that it becomes alkaline. In normal persons this result takes place, as has repeatedly been demonstrated, when from 5 to 10 gm. of the alkali are administered. It suggests that the kidneys secrete alkaline urine only when the level of the bicarbonate concentration of the blood reaches certain proportions. Palmer and Van Slyke[1] have remarked, in the course of a study of acidosis at the Hospital of the Rockefeller Institute, that to judge from the small amounts of bicarbonate required to turn the urine of normal men alkaline, this level would be appreciably, but not greatly, above the average normal. They have found, in accord with this, that under conditions of health there is a fairly definite level of the plasma bicarbonate at which the urine changes its reaction from one more acid than blood to one more alkaline. In normal men this occurred when the plasma bicarbonate (as CO_2) reached 71 ± 5 per cent. by volume. In the case of persons abnormal in health, there may be a different status of kidney permeability. In most of the pathologic cases studied at the Rockefeller Institute hospital, the urine did not become more alkaline than the blood until a higher plasma bicarbonate had been reached than in normal persons. It is evident, therefore, that the quantity of bicarbonate required in some pathologic conditions to produce an alkaline urine may give a false indication of the degree of acidosis or even the presence of such a condition; for, in some cases that belong to the group of abnormal persons, the plasma bicarbonate may rise appreciably higher than is normally the case before an alkaline urine begins to be excreted. Palmer and Van Slyke explain that herein may lie the true explanation of the objection that certain clinicians have registered against the liberal use of alkali therapy. If bicarbonate is given to patients in continued doses until the urine becomes alkaline, there is danger of administering unnecessary and perhaps even injurious amounts. Alkalosis, in contrast with acidosis, has lately been associated with tetany. There accordingly arises the necessity of carefully controlling the therapeutic use of sodium bicarbonate. This may best be done by determination of the plasma bicarbonate. It is improbable that more severe acidosis often exists than is indicated by the bicarbonate retention test in "titrating the body"; but

---

[1] Palmer, W. W., and Van Slyke, D. C.: Studies of Acidosis, IX, Relationship Between Alkali Retention and Alkali Reserve in Normal and Pathological Individuals, Jour. Biol. Chem., 1917, **32**, 499.

Palmer and Van Slyke now contend that it may be indefinitely less severe. As they express it, the alkali retention test, conducted by feeding bicarbonate until the urine shows an alkalinity approximating that of normal blood, indicates either the approximately correct alkali reserve, or less. If no acidosis is indicated by the test, its absence can therefore apparently be accepted; but if acidosis is indicated, the finding must be confirmed by blood analysis before being accepted.

SOME NUISANCES OF THE BATTLE FRONT

The dead bodies of animals or men exposed to the elements of nature without further attention become the occasion for much concern if they are in the neighborhood of human habitations. They afford a locus of dangers and nuisances arising in particular from putrefaction and flies. In war, the great toll of dead men and horses left to decay without special burial or treatment, presents a problem in sanitation that army officers are often compelled to face in a large way, whereas it is not infrequently present in the ordinary routine of every day peace-time experiences, though in less conspicuous guise. The stench of the battlefield and the swarms of insects that help in the work of final destruction of animal tissue have often been described. How to combat them effectively must doubtless be determined by the exigencies of the situation, which are quite different at the fighting front from what they are likely to be in an ordinary environment.

Foreman and Graham-Smith,[1] who have attempted to find easy and practicable means for mitigating the various nuisances arising from exposed animal matter, have lately conducted numerous experiments under field conditions. They have arrived at the conclusion that in the superficial treatment of intact or opened carcasses and other putrescible materials, reagents should be used which adhere to the greasy surfaces, form films, render the skin waterproof, and kill the bacteria in it, thus checking putrefaction by preventing the access of water and putrefactive organisms to the tissues. Further, the reagent should be a deodorant, capable of repelling flies which lay their eggs on animal matter, killing the eggs or larvae, resisting the action of water, and remaining operative in all respects for a long time. The British investigators state that watery emulsions of disinfectants are necessarily deficient in most of these properties. Only undiluted oily reagents possess them.

In the experience of Foreman and Graham-Smith, coal-tar creosote oil meets the needs just outlined most satisfactorily. Many other disinfectants have, of course, been tested here and abroad. The method reported is said to have advantage for a variety of purposes beside the treatment of dead bodies. Flies have been kept from entering such places as dugouts by means of sacks treated with creosote oil mixtures and hung over the entrance. Latrines have been kept free from flies by being sprayed with it. The enumeration of these few circumstances not only serves to indicate a practical management of serious difficulties of daily life, but also helps to remind us how greatly these become aggravated and magnified in the circumstances of war time. Yet they must be met.

THE BEHAVIOR OF CERTAIN VITAMINS

A recent study of one of the dietary essentials or vitamins which McCollum has designated temporarily as "water-soluble B" brings us appreciably nearer to a more precise understanding of these unique substances. Ever since the surprising descriptions of the almost miraculous relief of animals suffering from experimental polyneuritis by the administration of extremely small quantities of substances derived from rice polishings and other sources, the curiosity of both the physiologist and the clinician has been aroused at the possible chemical nature and mode of action of these so-called vitamins. Enough data furnished by competent workers now exist to indicate how essential these as yet unidentified components of the diet are for the physiologic well-being of the individual. Without certain additions, otherwise adequate mixtures of the familiar nutrients, proteins, fats, carbohydrates and inorganic salts, will not suffice to induce satisfactory nutrition. These additions, or vitamins, are widely distributed in the most diverse natural products. The absence of the dietary essentials results in nutritive decline, and a variety of pathologic consequences which are just beginning to be recognized as indications of dietary deficiences. McCollum and Simmonds[1] have found that the water-soluble B, the vitamin that averts symptoms of polyneuritis when the diet is otherwise adequate, can be extracted from diverse plant and animal sources by the use of alcohol. This procedure liberates the vitamin so that it becomes soluble in organic solvents like benzene, with which it cannot be extracted from its original sources. Thus it has been found that the water-soluble B is not extracted directly from beans, wheat germ, or pig kidney by ether, benzene or acetone, but is readily extracted in great part by alcohol. After being removed by alcohol, it is shown to be soluble thereupon in benzene, but very slightly soluble in acetone. The probability, McCollum and Simmonds state, that there should be two or more physiologically indispensable substances in what they term water-soluble B, both or all of which should show the same solubility relations with three solvents, is relatively small and lends support to their view that the substance which protects animals against polyneuritis is the only essential complex in the extracts described. In other words, the data support the view that there are no specific substances present in these extracts which protect against such diseases as scurvy, rickets, pellagra and sprue, and tend to confirm their contention that the latter are not due to specific starvation, as is the case with beriberi and xerophthalmia. The tentative exclusion of the hypothesis of a great multiplicity of vitamins marks an advance in the study of these diseases.

Medical Mobilization and the War

Navy Needs More Medical Reserve Officers

According to the *Army and Navy Journal*, examinations are to be held at each of the larger stations of the Navy to increase the strength of the Medical Reserve Corps of the Navy. The department needs 500 additional medical reserve officers, and it is stated that the men are needed for active duty as soon as they can be obtained.

American Prisoners Interned in Germany

Among the list of American prisoners who have been interned in Germany, as announced in the *Official Bulletin*, are the names of the following doctors: Dr. John Brown, taken from the Esmeraldas on March 10, 1917, interned at Camp Beeskow, home address, Hampton, Va.; Dr. John Davies, taken from the *Georgic* in the North Atlantic, Dec. 10, 1916, interned at Camp Karlsruhe, home address, Columbus, Miss.; and Dr. Herbert Snyder, taken from the *Voltaire*, Dec. 2, 1916, interned at Camp Karlsruhe, home address, Norfolk, Va. The Association's biographic records do not contain these names and addresses.

New Regulations Regarding the Mailing of Parcels to Members of the Expeditionary Forces

Under date of March 29, the Postmaster-General issued an order stating that on and after April 1, 1918, parcels for members and individuals connected with the American Expeditionary Forces in Europe shall not be accepted for mailing or dispatching unless they contain such articles only as are being sent at the written request of the addressee, approved by his regimental or higher commander or an executive officer of the organization with which he is connected. In enforcing this order, postmasters are instructed to secure the assurance of the sender in each case that all the articles contained in the parcels are sent at the addressee's approved written request, that such request is enclosed in the parcel, and to require the sender to place on the wrapper of the parcel under his name and address the following endorsement: "This parcel contains only articles sent at the approved request of addressee which is enclosed." The postoffice order is issued at the request of the War Department.

Personnel of the Medical Department

For the week ending March 29, the personnel of the Medical Department of the Army included:

Medical Corps: 827, including 1 major-general, 66 colonels, 102 lieutenant-colonels, 176 majors, 3 captains and 479 lieutenants.

Medical Reserve Corps: 18,206, including 1,107 majors, 4,246 captains and 12,853 lieutenants. On active duty: 15,174, including 986 majors, 3,727 captains and 10,461 lieutenants.

Medical Corps, National Guard: 1,229, including 15 lieutenant-colonels, 253 majors, 150 captains and 811 lieutenants.

Medical Corps, National Army: 93, including 3 brigadier-generals, 11 colonels, 72 lieutenant-colonels and 7 majors.

Dental Corps, 209; Dental Reserve Corps, 5,153, of whom 1,343 are on active duty; Dental Corps, N. G., 259; Veterinary Corps, 24; Veterinary Reserve Corps, 1,426, of whom 823 are on active duty; Veterinary Corps, N. G., 57; Veterinary Corps, N. A., 296; Sanitary Corps, 1,017, and Ambulance Service, 143, constitute the remainder of the commissioned personnel.

The DISCHARGES in all branches of the service to date are:

	Number			
Causes	*MRC*	*MC,NG*	*DC,NG*	San. C.
Physical disability	476	35	6	4
Inaptitude	190	10	0	1
Other branches of the service	383	19	2	42
Domestic troubles	30	0	0	1
Needed by the community	35	1	0	0
Deaths	43	3	0	0
Dismissals	2	2	0	0
Resignations	142	43	5	8
	1,301	113	13	56

Distinguished Service Awards for Medical Officers

It is reported that distinguished service crosses have been awarded to two American medical officers for exceptional performances. One is given as "Lieut. H. R. Davies, M. R. C.," of Charleston, S. C., who is serving with the British Army. It is stated that on January 8 he entered a dugout under conspicuous fire, remained there attending the occupants after it had been blown in, performed an amputation and saved the life of a British soldier, and that previous to this time he had taken a prisoner in a listening post in the Toul sector. It is stated that this is the first medal conferred on an American serving with the British forces. The biographic department of the Association does not record any physician of this name and address.

It is also reported that a distinguished service cross has been awarded to Lieut. J. P. Rosenwald, M. C., N. G., U. S. Army, for duty performed during the fighting on the Luneville sector. Lieutenant Rosenwald, while attached to an artillery regiment, twice entered a battery position under heavy fire in order properly to care for the wounded. Lieut. John Paul Rosenwald, Minneapolis, is 34 years old. He graduated from the John A. Creighton Medical School in Omaha in 1910 and is a Fellow of the American Medical Association.

New Legislation

During the week ending March 30 several bills were introduced into the Congress, which concern the Medical Department.

BILLS PASSED

Army Nurse Corps.—The Senate passed Senate Bill 3693 prescribing the personnel of the Army Nurse Corps, the qualifications for appointment, method of appointment, pay, allowances and leave, and the conditions under which nurses may be retired.

Commutation of Quarters.—The Senate also passed Senate Bill 3863 providing for commutation of quarters during the present emergency for every commissioned officer of the Army of the United States on duty in the field or on active duty outside of the United States who maintains a place of abode for a wife, child or dependent parent.

BILLS INTRODUCED

Rank and Pay of the Medical Department.—Senate Bill 4168 was introduced into the Senate by Senator J. K. Shields of Tennessee, which provides:

> "That the Medical Department of the Army shall consist of one surgeon general with the rank of major general, who shall be chief of said department; six assistant surgeons general, the assistant surgeons general to be equally distributed in the grades of major general and brigadier general; the Medical Corps; the Medical Reserve Corps; the Dental Corps; the Dental Reserve Corps; the Veterinary Corps; the Veterinary Reserve Corps, the commissioned officers of which shall be citizens of the U. S.; the Nurse Corps and contract surgeons authorized by law; the enlisted force of the Medical Department of the Army; and the Medical Enlisted Reserve Corps, as now provided by law. Commissioned officers of Medical Corps below rank of brigadier general shall be proportionately distributed in the several grades as now provided by law. The commissioned officers of Medical Reserve Corps shall be distributed in the several grades as in Medical Corps of Army. In time of war the President shall have authority to appoint in grade of consultant, to be equally distributed in grades of major general and brigadier general, such number of officers of Medical Reserve Corps as interests of service may demand: Provided, That reserve officers so appointed shall at no time exceed twenty in number. Nothing in this Act shall be held or construed so as to discharge any officer of the Regular Army or deprive him of a commission which he now holds therein."

To Furnish Uniforms.—H. R. 10925 was introduced into the House of Representatives by R. L. Doughton of North Carolina,

> "To furnish all uniforms, accouterments and equipments required for any officer of the military forces of the United States at cost prices."

H. R. 10976 was also introduced by Mr. Doughton:

> "Requiring the Government to furnish uniforms to officers of the Army or Navy, and for other purposes."

Filling Vacancies in Medical Department.—H. R. 10928 was introduced by L. C. Dyer of Missouri, which provides:

> "That hereafter the President shall be authorized to fill any vacancies that may occur in the commissioned personnel of the Medical Department of the Army by ordering such officers of the medical section, officers' Reserve Corps and Dental Reserve Corps, who shall have been in active service one year or more, to the Army Medical School or Army Dental School under such rules and regulations as shall be prescribed by the Secretary of War, and such officers so ordered, upon completion and satisfactory examination, shall be commissioned first lieutenants in the Medical Department, U. S. Army, and be entitled to all the pay, promotion and allowances of officers of like rank in the Army of the U. S., except that the rate of retirement shall be one-thirtieth of the present retirement pay as now prescribed by law for each year's active service as an enlisted man, contract surgeon, or as a commissioned

officer in the Army of the U. S., medical section, Officers' Reserve Corps, Medical Reserve Corps, Dental Reserve Corps, or Organized Militia in Federal Service: Provided, That at the age now prescribed by law for retirement every officer to be so commissioned shall have had not less than fifteen years' active service in any of the branches enumerated in this Act: Provided further, That preference for appointment shall be given to those who have had the longest aggregate active service in the branches enumerated in this Act."

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending March 22, 1918

1. ANNUAL ADMISSION RATE PER 1,000 (DISEASE ONLY):

All troops	1,464.2
National Guard Camps	893.6
National Army Camps	1870.
Regular Army	1,390.2

2. NONEFFECTIVE RATE PER 1,000 ON DAY OF REPORT:

All Troops	48.7
National Guard Camps	37.8
National Army Camps	57.
Regular Army	43.

3. ANNUAL DEATH RATE PER 1,000 (DISEASE ONLY):

All Troops	8.9
National Guard Camps	2.8
National Army Camps	13.1
Regular Army	9.3

NEWS OF THE CANTONMENTS

Eighty-Third Division, Camp Sherman, Chillicothe, Ohio

MARCH 26, 1918.

INFECTIOUS DISEASES

Until well into January the camp was comparatively free from the infectious diseases. During January there were 2 cases of chickenpox, 627 of measles, 368 of mumps, 41 of pneumonia, 81 of scarlet fever, 5 of epidemic meningitis and 21 of diphtheria. During February there were 3 cases of chickenpox, 298 of measles, 897 of mumps, 50 of pneumonia, 142 of scarlet fever, 4 of epidemic meningitis and 14 of diphtheria. The incidence of sore throats and tonsillitis increased, and there were 583 reported cases. Up to February there were 42 deaths, and in that month 12 were added; a small list considering the duration of the camp and the number of men who have been ill in that time.

The large number of sick made it necessary to provide more quarters, as the base hospital capacity is a limited factor, and these quarters were provided by the opening of a convalescent hospital in four barracks. This hospital was placed under the management of the sanitary train, which obtained an invaluable opportunity for instruction of both officers and men.

PROMOTION

Major Henry S. Satterlee, commanding officer of the sanitary train, has been promoted to the rank of Lieutenant-Colonel in the National Army, as required by the new tables of organization.

CONFERENCES

During February, conferences were held by a representative of the division surgeon's office with the members of the advisory and local boards of the selective service in the various districts of Ohio and western Pennsylvania. The effect of such conferences should be evident in the diminished number of men rejected at camp for evident physical defects.

Under the new authorizations, it will be possible to have groups of men with similar physical defects and to assign medical officers to supervise the therapeutic instruction of the groups, prescribing the type of and duration of exercises.

TUBERCULOSIS

The special board examining for tuberculosis has found only 381 cases of pulmonary disease; of the diseases found, 2.84 per thousand were tuberculosis; 3.34 per thousand were cardiovascular defects, and all other defects amounted to 0.979 per thousand.

PERSONAL

Major E. G. Huber, M. C., commanding officer of the base hospital, has been promoted to the rank of Lieutenant-Colonel, and will visit other base hospitals for observational and educational purposes.

Lieut.-Col. Allen B. Tucker of the sanitary corps has been sent to Camp McClellan, Anniston, Ala., to take up the fight against mosquitoes.

Capt. Charles A. Haskins has been sent here in his place as assistant to the sanitary inspector, Major J. H. Burkett.

Majors Harry M. Hosmer and Alfred Friedlander have been on a visit to other base hospitals for the opportunity of learning how the medical surgical services are organized.

Several of the chiefs of services from other base hospitals have been here for a similar purpose. Such opportunities will be of the greatest value to both the visitor and the visited.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

April 1, 1918.

COURT MARTIAL OF LIEUT.-COL. JOHN H. ALLEN, M. C.

Charges which grew out of the discharge of Private Otho Murray, the drafted man who had Landry's paralysis, and for which Major Board has already been tried by a court martial, caused the court martial of Lieut.-Col. John H. Allen, M. C., former division surgeon, now camp surgeon at Camp Zachary Taylor.

The two charges against Lieutenant-Colonel Allen are that he violated the ninety-sixth article of war, for the reason stated above, and that he was guilty of insubordination and disrespect to the commanding general in writing a letter to Major Arthur T. McCormack at Washington, regarding Major Board's connection with the case of Otho Murray.

The letter that was submitted as evidence was written before the trial of Major Board, and was in regard to the trial. It is charged by the prosecution that Lieutenant-Colonel Allen wrote this letter for the purpose of having the trial of Major Board thrown out of court. The prosecution also claimed in regard to the letter that the judge advocate, who was a member of the investigating committee, was ridiculed and criticized by Colonel Allen, when he referred to 2 c.c. being drawn from the spinal canal of Private Murray as compound cathartics. On the court trying Lieutenant-Colonel Allen are one brigadier-general, four colonels, and three lieutenant-colonels.

NUTRITIONAL SURVEY

The nutritional survey party which was sent to Camp Zachary Taylor five weeks ago by Surgeon-General Gorgas to investigate into food conditions here will complete its task within a week and report through Division Surgeon Col. William M. Smart to the Surgeon-General. The members of the board are physicists and chemists. They are Capt. R. G. Hoskins, Capt. Leon S. Congdon, Lieut. F. A. Cajori and Lieut. A. G. Hogan.

Some suggestions have been made for messes to balance the menu better. The members of the board decline to discuss what their report will be concerning food conditions here. They completed surveys at four other cantonments before coming to Camp Zachary Taylor.

The new division sanitary officer, Val E. Miltenberger, is receiving congratulations on his promotion. He was a first lieutenant in the Regular Army when he came here last week from Camp Dix. He jumped the grade of captain and was commissioned a major in the National Army.

Major Luther R. Poust, assistant to the camp surgeon, Lieut.-Col. John H. Allen, has returned from a leave of ten days spent in the East and resumed his official duties.

Since his return, Major Poust has been promoted to lieutenant-colonel. He was one of the first officers here, having been in charge of sanitation during the construction period. Recently he was relieved of his duties as sanitary officer and made assistant to the camp surgeon, Lieut.-Col. John H. Allen.

On recommendation of Lieut.-Col. William Smart, surgeon of the Eighty-fourth (Lincoln) Division, Capt. David C. Donan was transferred from the base hospital to the Three Hundred and Thirty-Sixth Infantry Regimental Infirmary.

BASE HOSPITAL UNITS

Major Leonard S. Hughes, who will command Base Hospital Unit No. 40, has arrived and assumed his duties. He was educated in Louisville and is a veteran of the Spanish-American War. The unit was organized at Lexington, and its enlisted personnel includes scions of some of the oldest and foremost families of the Blue Grass State.

There are now three base hospital units at the cantonment, and nearly as many commissioned officers filling each position at the hospital. These officers are receiving valuable experience and training in this manner, while the patients are benefited by the combined medical skill. When orders are received for a hospital unit to go forward, the commissioned personnel will have a thorough knowledge of the work, and its removal will not interfere with the efficiency of the force at the local hospital. Only two of the base hospital units ve been completely organized, the commissioned personnel he third having been formed "on paper." A large inflow edical officers is expected here next week.

PRISONERS' WARD

ormai.
harlesto.

ment have been completed for a special ward at the l at Camp Zachary Taylor for the care and confinement of sick prisoners. Lieut.-Col. Will Pyles, superintendent, has received official notification from the Surgeon-General that the recommendation for the prisoners' ward has been approved and authorization given for its construction.

The building will be more substantial than other wards as a precautionary measure against escape of prisoners, and the windows will be barred. It will cost approximately $5,000. The site has not been selected, but it will probably be within the hospital area along Washington Avenue (formerly Bickel Lane), between the Preston Street road and Lincoln Avenue.

The new ward will alleviate a situation that has caused considerable inconvenience and handicap to the hospital officers and attachés. Whenever a military prisoner is stricken ill and removed from a guardhouse to the hospital it becomes necessary to station a guard at his bedside night and day to thwart any attempt at escape that might be made.

The new prisoners' department will have a general ward for treatment of medical and surgical patients and isolated rooms for those suffering from contagious diseases. It will all be under one roof. A few guards will be able to watch and control all the patients. It is expected that work on the structure will be started at an early date and rapidly pushed to completion. It has been announced that an extension will be added to the eye, ear, nose and throat building at the base hospital, and that an isolation ward for nurses suffering from contagious diseases will be erected.

Eighty-Sixth Division, Camp Grant, Rockford, Ill.

March 28, 1918.

DISEASE RATE

Camp Grant has set a mark the past week for all of the National Army cantonments to shoot at, and it is safe to predict that bull's-eyes will be few and far between. A noneffective rate of 28.3 per thousand and an annual admission rate of 783 per thousand will prove thorns in the side of many aspiring camps for some time to come. Further comment on disease conditions at Camp Grant is unnecessary.

INSPECTION

Another inspection has been passed in safety. Col. A. E. Truby was the ogre this time, but there was no necessity to call for a Siegfried. Contrary to the usual custom of inspectors, his comments on the excellence of the medical aspects of the camp were many, and on the other hand, there were but few things calling for adverse comment.

SOCIETY

A dinner and theater party was tendered by Lieut.-Col. James M. Phalen, division surgeon, to the surgeons of the divisional organizations last week as a windup of a series of weekly dinners and meetings that has been held each Thursday night at the different regimental infirmaries throughout the division. As a result of these informal gatherings, an unusual esprit de corps has arisen, welding the sanitary phase of the Eighty-Sixth Division into a compact body, inspired with the determination to maintain the axiom that the "Eighty-Sixth Division cannot be surpassed." At Colonel Phalen's dinner, to quote the words of the editor of the Podunk *Weekly Squeegee*, a good time was had by all.

PROMOTIONS

Promotions have been coming like Portia's "rain from Heaven." Major G. L. McKinney, M. C., sanitary inspector, was the guest of Colonel Raymond of the Central Department at a little lieutenant-colonelcy examination party recently and his promotion is hourly expected. The commanding officer of the sanitary train received an electroplating wire from Washington several weeks ago that transformed his gold leaves to silver, and he is now addressed as Lieut.-Col. S. J. Kopetzky, M. C. N. A. Major A. Schuyler Clark is understudying Lieutenant-Colonel Michie in the rôle of commanding officer of the base hospital, and the directorship of the field hospital section of the sanitary train has fallen on the shoulders of Major E. A. Spitzka of anatomic fame. Promotions to the rank of Major, M. R. C., have been received by: H. H. Thompson, surgeon, Three Hundred and Forty-Second Infantry; D. H. Silsby, surgeon, Three Hundred and Forty-Fourth Infantry; C. C. Vogel, surgeon, Three Hundred and Thirty-First Field Artillery; J. D. Dallenbach, surgeon, Three Hundred and Thirty-Second Field Artillery; F. Deacon, surgeon, Three Hundred and Thirty-Third Artillery, and H. S. Gradle, assistant to the division surgeon.

ORDERS TO OFFICERS OF THE MEDICAL CORPS AND OF THE MEDICAL CORPS OF THE NATIONAL ARMY

To Camp Fremont, Palo Alto, Calif., as commanding officer of base hospital, from San Francisco, Col. EUCLID B. FRICK.

To Camp Jackson, Columbia, S. C., *Camp Hancock*, Augusta, Ga., *Camp Wheeler*, Macon, Ga., *Camp Sheridan*, Montgomery, Ala., *Camp Beauregard*, Alexandria, La., *Sheffield, Ala.*, for inspection, and on completion *to his proper station*, Col. JOSEPH R. WHITE.

To Camp Upton, Yaphank, L. I., N. Y., for inspection, and on completion *to his proper station*, Col. PERCY M. ASHBURN.

To Fort Oglethorpe as commanding officer, United States Army General Hospital, from Fort Oglethorpe, Col. HENRY P. BIRMINGHAM.

To Fort Riley for inspection of medical officers, and on completion *to his proper station*, Col. EDWARD L. MUNSON. Base hospital, from San Francisco, Major FLETCHER O. McFARLAND.

To Camp Dix, Wrightstown, N. J., *Mineola*, L. I., N. Y., *New York City*, *Lakewood*, *N. J.*, for inspecting cardiovascular work, and on completion *to his proper station*, Lieut. Col. WARFIELD T. LONGCOPE. *To Camp Dix* for temporary duty, from Camp Doniphan, Lieut. Col. SAMUEL S. CREIGHTON. To assist camp surgeon, from Camp Devens, Major JOSEPH L. SINER.

To Camp Lee, Petersburg, Va., *Camp Meade*, Annapolis Junction, Md., *Camp Dix*, Wrightstown, N. J., base hospitals, and on completion *to his proper station*, from Camp Greene, Lieut.-Col. WILLIAM L. SHEEP.

To Camp Zachary Taylor, Louisville, Ky., *Camp Lee*, Petersburg, Va., *Camp Meade*, Annapolis Junction, Md., base hospitals, and on completion *to his proper station*, from Camp Sherman, Lieut.-Col. EDWARD C. HUBER.

To Hoboken, N. J., for duty, from San Francisco, Lieut.-Col. HENRY H. RUTHERFORD; from Fort Hamilton, Lieut. ERNEST H. SANITOR; from Rockefeller Institute, Lieut. VIRGIL H. CORNELL.

To Mineola, L. I., N. Y., for inspection and on completion *to his proper station*, Lieut.-Col. WALTER R. PARKER.

To Camp Grant, Rockford, Ill., base hospital, from San Francisco, Major ROBERT H. WILDS.

To Colonia, N. J., for duty, from Camp Pike, Major ALFRED P. UPSHUR.

To Gettysburg, Pa., as camp surgeon, from Camp Dix, Major DOUGLAS W. McENRY.

To Norfolk, Va., as sanitary inspector, from Camp Sevier, Major JAMES R. MANKIVELL.

To Rockefeller Institute for instruction in the serum therapy of pneumonia, from Camp Sherman, Major ALEXANDER W. WILLIAMS.

To Camp Logan, Houston, Texas, base hospital, from Camp Logan, Lieut. GEORGE U. LIPSHULCH.

To Chickamauga Park, Ga., for duty, from Fort Oglethorpe, Lieut. FREDERICK T. HILL.

To New Haven, Conn., for duty, from Williamsbridge, Lieut. ARDEN PREER.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Camp McClellan, Anniston, Ala., *Camp Pike*, Little Rock, Ark., *Camp Shelby*, Hattiesburg, Miss., base hospitals, and on completion *to his proper station*, from Camp Sheridan, Major JAMES S. McLESTER, Birmingham.

To Camp Meade, Annapolis Junction, Md., as member of the board of medical officers to examine the command for tuberculosis, from Fort Oglethorpe, Lieut. BURTON F. AUSTIN, Mobile.

To Camp Sheridan, Montgomery, Ala., base hospital, from St. Louis, Lieut. LEMUEL B. NICHOLSON, Gadsden.

To Colgate Creek, Md., for duty, from Fort Oglethorpe, Capt. JOHN McI. WHITESIDE, Anniston.

To Dallas, Texas, Aviation Repair Depot, for duty, from Birmingham, Capt. GASTON W. ROGERS, Birmingham.

To Fort Oglethorpe for instruction, Lieuts. JOSEPH W. HUGHES, Birmingham; RALPH M. KIMBROUGH, Thomasville; from Camp Sheridan, Lieuts. BENJAMIN E. GRAHAM, Gurley; JAMES R. HAIGLER, Montgomery.

To Fort Riley for instruction, from Fort Riley, Lieut. RUSSELL CALLEN, Birmingham.

To [illegible] Y., Hazelhurst Field, Capt. KOSCIUSKO [illegible] irmingham.

To [illegible] Hospital for instruction, and on completion *to Camp MacArthur*, Waco, Texas, base hospital, from Fort Oglethorpe, Lieut. THOMAS C. SAVAGE, Demopolis.

To New York City, Cornell Medical College, for instruction in military roentgenology, from Fort Riley, Lieut. DUKE C. BRADFORD, Springville.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieut. WILLIAM A. STANLEY Enterprise.

Resignation of Lieut. CLARK HILL, Cance, accepted.

Arizona

To Camp Bowie, Fort Worth, Texas, base hospital, from St. Louis, Lieut. GEORGE W. PURCELL, Tucson.

To Fort Riley for instruction, from San Antonio, Lieut. SPENCER D. WHITING, Phoenix.

To Washington, D. C., for temporary duty, from Washington, Capt. FREDERICK T. WRIGHT, Douglas.

Arkansas

To Camp Dodge, Des Moines, Iowa, for duty, from Fort Riley, Lieut. JAMES W. SLAUGHTER, Wesson.

To Camp Pike, Little Rock, Ark., base hospital, from St. Louis, Capt. SCOTT C. RUNNELLS, Little Rock.

To Camp Wheeler, Macon, Ga., base hospital, from St. Louis, Lieut. WALLACE D. ROSE, Little Rock.

To Fort Oglethorpe for instruction, from Camp Beauregard, Capt. JOHN H. BELL, Arkadelphia.

To Fort Riley for instruction, Lieut. ALBERT E. TATMAN, Eureka Springs.

To Jefferson Barracks, Mo., for duty, from Camp Pike, Capt. WILLIAM K. READ, Texarkana.

To San Antonio, Texas, Kelly Field, for duty, from Fort Riley, Lieut. R. NEWMAN BROWN, McGehee.

Canal Zone

To Panama Canal Department for duty, Lieut. JOHN D. ODOM, Cristobal.

California

To Camp Doniphan, Fort Sill, Okla., base hospital, from Fort Riley, Lieut. BENJAMIN E. MERRILL, Santa Paula.

To Camp Fremont, Palo Alto, Calif., base hospital, Capts. FRED P. BOWEN, Los Angeles; HERBERT A. MAKINSON, Oakland; SYLVAN L. HAAS, San Francisco; Lieuts. FRED O. BUTLER, Eldridge; HARRY J. CRAYCROFT, Fresno; CHARLES W. HARRISON, Loma Linda; WINFIELD L. BARTOW, ARTHUR L. PETER, Los Angeles; EARL B. FITZGERALD, Martinez; EDWIN R. FOUNTAIN, Merced; GEORGE T. WILHELM, Porterville; ERVIN J. CASPER, HERBERT J. COHN, EDWARD J. GHIDELLA, MELVILLE H. LONG, San Francisco; THOMAS L. BLANCHARD, San Jose.

To Camp Grant, Rockford, Ill., base hospital, Lieut. BRUCE McV. MacKALL, San Francisco.

To Camp Kearny, Linda Vista, Calif., as members of a board of medical officers to examine the command for tuberculosis, Capt. CHARLES E. IDE, Redlands; Lieut. LESTER E. TRETHAWAY, French Camp. Base hospital, Lieuts. PAUL E. DOLAN, Livermore; OTTO D. CHAMLEY, Los Angeles; EVERETT E. GRAY, Marysville; FRANK J. TILLMAN, Oxnard; ROBERT K. MACKLIN, Pasadena; GEORGE C. WRIGLEY, Sonora; HOMER R. EVANS, Trona.

To Camp Lee, Petersburg, Va., base hospital, Lieut. FREDERICK M. GODNEY, San Francisco.

To Camp Lewis, American Lake, Wash., base hospital, Lieut. WALLACE A. REED, Covina.

To Fort Oglethorpe for instruction, from St. Louis, Capt. CHARLES J. [illegible]

To [illegible] uction, Lieuts. ANGUS A. MacLENNAN, Los Angeles; from Camp Bowie, Lieut. FRANK A. WOODWARD, Los Angeles; from Camp Kearny, Lieut. JOHN P. JONES, National Soldiers Home.

To Fort Sam Houston, Texas, base hospital, Lieut. JOHN H. SCHAEFER, Kerman.

To Los Angeles, Calif., Camp Arcadia, for duty, from Los Angeles, Capt. ARTHUR N. BOBBITT, San Diego.

To Mineola, L. I., N. Y., for duty, Capt. JOSEPH E. GRANT, San Diego.

To report by wire to the Commanding General, Western Department, for assignment to duty, Capt. ROBERT B. DIMON, Los Angeles.

Honorably discharged on account of physical disability existing prior to entrance into the service, Capts. FRANK DUNLAP, Brawley; JESSE M. BURLEW, Santa Ana.

Colorado

To Camp Beauregard, Alexandria, La.; *Camp MacArthur*, Waco, Texas; *Camp Travis*, Fort Sam Houston, Texas, base hospitals, and on completion *to his proper station*, from Camp Logan, Major JOSIAH N. HALL, Denver.

To Camp Cody, Deming, N. M., base hospital, from Chicago, Major EDWARD F. DEAN, Denver.

To Camp Crane, Allentown, Pa., for duty, from Camp Custer, Lieut. ROBERT R. PACKARD, Denver.

To Camp Dodge, Des Moines, Iowa, base hospital, from Fort Riley, Lieut. CARL W. SLUSSER, Denver.

To Camp Grant, Rockford, Ill., base hospital, Major CHARLES F. STOUGH, Colorado Springs.

To Fort Logan, Colo., for duty, Capt. JOHN GORSUCH; Lieuts. CHARLES W. METZ, HARRY S. SHAFER, Denver.

To Fort Riley for instruction, Capt. VICTOR B. AYERS, Buena Vista; Lieuts. CHARLES L. ORR, Alomosa; CLARENCE M. FROID, Central City; LOUIS G. BROWN, Colorado Springs; EARLSCOURT G. SHAFFER, Delta; WILLIAM D. FLEMING, ELBERT B. SWERDFEGER, Denver; JOSEPH R. HOOD, Golden; ARTHUR G. TAYLOR, Grand Junction; CLYDE T. KNUCKEY, Lamar; VIVIAN R. PENNOCK, Longmont; ROBERT C. BOWIE, Morgan; JULIAN C. KENNEDY, Oak Creek; AUGUSTUS F. ERICH, Paonia; ORTUS F. ADAMS, Segundo; FRANK J. BLACKMER, Steamboat Springs.

To Fort Sam Houston, Texas, base hospital, from Fort Oglethorpe, Lieut. JOSEPH A. KELLY, Oak Creek.

Physically incapacitated for active service, Lieut. BERT MENSER, Denver.

Discharged, according to cable received from General Pershing, Major EDWARD WILLIAM LAZELL, Denver.

Connecticut

To Camp Dix, Wrightstown, N. J., as assistant to the orthopedic surgeon in the camp, from Fort Oglethorpe, Lieut. EWALD E. OLSSON, Bridgeport.

To Camp Greene, Charlotte, N. C., base hospital, from Camp Greene, Lieut. FRANK E. WILSON, Hartford.

To Lake Charles, La., Signal Corps Aviation School, from Fort Oglethorpe, Lieut. LONNIE M. McMILLAN, Florence.

South Dakota

To Fort Riley for instruction, Capt. WILLIAM E. FEHLIMAN, Lead; Lieuts. DENNIS W. SULLIVAN, Britton; W[illegible] BALL, Mitchell; CLEVELAND F. BROOKS, Platte; [illegible] PINARD, Wagner.

Tennessee

To Camp Custer, Battle Creek, Mich., as a member of the board for the examination of the command for tuberculosis from Fort Oglethorpe, Lieut. ENOCH C. SEALE, Nashville.

To Camp Doniphan, Fort Sill, Okla., base hospital, from Fort Riley, Lieut. SALVADOR L. BOCCELLATO, Memphis.

To Camp Greene, Charlotte, N. C., base hospital, from St. Louis, Capt. BERNARD C. McMAHON, Memphis.

To Camp McClellan, Anniston, Ala., for duty, from Fort Oglethorpe, Lieut. HARRY L. LOTT, Knoxville.

To Chickamauga Park, Ga., for duty, from Fort Oglethorpe, Lieut. IRA J. TATUM, Gleason.

To Fort Dade, Fla., for duty, from Fort Oglethorpe, Lieut. GEORGE E. KERR, Chattanooga.

To Fort Oglethorpe for instruction, Lieut. JESSE A. JAMES, Nashville.

To Fort Riley for instruction, Lieut. GRANVILLE D. LEQUIRE, Rutledge.

Texas

To Camp Bowie, Fort Worth, Texas, base hospital, Lieut. ELMER W. JONES, Wellington; from Chicago, Lieut. FRANK G. SANDERS, Fort Worth.

To Camp Crane, Allentown, Pa., for duty, from Washington, Lieut. QUINCY B. LEE, Wichita Falls.

To Camp Hancock, Augusta, Ga., for duty, from Camp Hancock, Lieut. HOWARD L. FARQUHAR, West Brownville.

To Camp Joseph E. Johnston, Jacksonville, Fla., for duty, from Southern Department, Capt. ARTHUR W. C. BERGFELD, Seguin.

To Camp MacArthur, Waco, Texas, base hospital, from Chicago, Capt. WILLIAM L. CROSTHWAIT, Waco.

To Camp McClellan, Anniston, Ala., for duty, from Fort Oglethorpe, Lieut. WILLIAM A. CHERNOSKY, Rosebud.

To Camp Sevier, Greenville, S. C., as orthopedic surgeon, from Camp Travis, Major CHARLES S. VENABLE, San Antonio.

To Camp Travis, San Antonio, Texas, base hospital, from Chicago, Capt. BERNARD F. SMITH, San Antonio.

To Fort Oglethorpe for instruction, Capts. ADDISON L. LINCECUM, Austin; SIDNEY J. FRANCIS, Luling; from St. Louis, Capt. IRA E. PRITCHETT, Houston. For instruction, Lieut. MILTON M. GLOVER, Wichita Falls; from Camp Hancock, Lieut. KNIGHT W. FIELD, Dallas; from Camp Pike, Lieut. CHARLES O. ADAMS, Longview; from San Antonio, Lieut. HALL SHANNON, Dallas.

To Fort Riley for instruction, from Fort Sill, Capt. FOSTER R. WINN, Alvin; from Camp Bowie, Lieut. JOHN R. LEWIS, Gainesville; from Camp Logan, Lieut. HENRY E. BAYLIS, Huntsville; from Camp MacArthur, Lieuts. SAM R. GRIFFIN, Canyon; WILLIAM E. CAMPBELL, Cedar Creek; SILAS G. CAIN, *Haskell;* WALTER PURVIANCE, Pampa; from Fort Sill, Lieut. OZRO W. CUNNINGHAM, Valley View.

To Fort Sam Houston, Texas, for duty, from Fort Riley, Lieut. LYLE J. LOGUE, Houston.

To New Orleans, Charity Hospital, for instruction, and on completion *to Camp MacArthur,* Waco, Texas, base hospital, Capt. DAVID H. LAWRENCE, El Paso. On completion *to Camp Shelby,* Hattiesburg, Miss., base hospital, Lieut. GEORGE T. THOMAS, Amarillo.

To New York City, Cornell Medical College, for instruction in military roentgenology, from Fort Riley, Lieut. JAMIE D. STEPHENS, Temple.

To San Antonio, Texas, Kelly Field, from San Antonio, Lieut. EDWARD E. COLLINS, Premont.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieuts. GEORGE W. HOWARD, Dallas; JAMES S. BUIE, Hillsboro; TALBERT M. HALL, Osage.

Resignation of Lieut. FRANCIS C. GREEN, Oglesby, accepted.

Utah

To Fort Riley for instruction, Capt. JOHN C. EVANS, Salt Lake City; Lieuts. JOSEPH E. DAY, *Garland City;* JOSEPH H. PECK, Gold Hill; THOMAS W. STEVENSON, Salt Lake City.

To Philadelphia, Pa., for orthopedic instruction, from Camp Travis, Lieut. DAVID K. ALLEN, Salt Lake City.

Virginia

To Camp Gordon, Atlanta, Ga., as assistant to the camp surgeon, from Camp Gordon, Major FREDERIC ELMER JENKINS, *National* Soldiers' Home.

To Camp Sevier, Greenville, S. C., base hospital, from Camp Sevier, Lieut. WILLIAM B. PORTER, Richmond.

To Chickamauga Park, Ga., for duty, from Fort Oglethorpe, Lieut. WADE C. PAYNE, Haymarket.

To Fort McHenry, Md., for duty, Lieut. ADRIAN VAN B. ORR, Chester.

To Fort Oglethorpe for instruction, from Camp Lee, Majors SAMUEL B. MOORE, Alexandria; ALLEN J. BLACK, Hollins; Lieut. ISAAC H. GOLDMAN, Richmond. For instruction, Lieut. WAVERLY S. TUCKER, Richmond; *from* St. Louis, Lieut. ELIJA M. HICKS, Roanoke.

To Fort Sam Houston, Texas, for temporary duty, Capt. JOHN M. LOVE, Norfolk.

To Rockefeller Institute for instruction in laboratory work, and on completion *to Army Medical School,* for duty, *Lieut.* JOHN E. WINE, Forestville.

Honorably discharged, Lieut. ALVAH RAMSEY, Burkesville.

Washington

To Camp Fremont, Palo Alto, Calif., base hospital, Lieut. CHARLES B. COWAN, Seattle.

To Camp Lewis, American Lake, Wash., base hospital, Lieut. HINTON D. JONES, Tacoma; from *Camp Lewis,* Lieut. CHARLES R. McCREERY, Tacoma.

To Fort Riley for instruction, from Camp Lewis, Capt. WILLIAM H. AXTELL, Bellingham; Lieut. JOSEPH S. SMEALL, Tacoma. For instruction, Lieut. CHARLES H. DEWITT, Jr., Tacoma.

To New York City, Cornell Medical College, for instruction in military roentgenology, from Fort Riley, Capt. FRANK L. WOOD, Lyden; from Portland, Ore., Lieut. FRANK A. BRYANT, Colfax.

To Seattle, Wash., University of Washington, for duty, and *on* completion *to Camp Fremont,* Palo Alto, Calif., base *hospital,* Major JAMES B. EAGLESON, Seattle.

West Virginia

To Camp Morrison, Va., for duty, from Pittsburgh, Lieut. RALPH H. BOICE, Sistersville.

To Los Angeles, Calif., Arcadia, for duty, from Los Angeles, Lieut. HARRY R. PARKER, Williamson.

Honorably discharged, on account of physical disability existing prior *to entrance into the service,* Capts. CALVIN M. KESSLER, Clarksburg; WILLIAM L. RAYL, *Huntington;* Lieut. NOAH E. STEELE, Omar.

Wisconsin

To Camp Bowie, Fort Worth, Texas, base hospital, from Fort Riley, Capt. VERNON ROBERTS, National Home.

To Camp Logan, Houston, Texas, *for duty, from* Fort Riley, Lieut. GEORGE R. REAY, LaCrosse.

To Camp Pike, Little Rock, Ark., to examine the troops for cardiovascular diseases, Capt. JAMES G. TAYLOR, Milwaukee.

To Chicago, Ill., Presbyterian Hospital, for instruction, and on completion *to Fort Riley,* base hospital, Capt. WILLIAM B. McCAULEY, Milwaukee. On completion *to Camp Grant,* Rockford, Ill., Lieut. EDMUND H. MENSING, Milwaukee.

To Fort Oglethorpe for instruction, from Fort Riley, Major EDWARD J. BARRETT, Sheboygan; *from* Chicago, Lieut. GEORGE H. SCHLESSELMAN, Fond du Lac.

To Fort Riley for instruction, Capts. ENOCH P. WEBB, Beaver Dam; BENJAMIN FOSSE, Beloit; HERMAN HENDRICKSON, Green Bay; GEORGE W. FIFIELD, Janesville; CHARLES R. LOCKWOOD, Kankakee; JOHN W. BIRD, Stevens Point; EUGENE GATES, Two Rivers; RICHARD E. DAVIES, Waukesha; Lieuts. FRANK C. WALCH, Black Creek; HAROLD KALLING, Black River Falls; WILLIAM H. BAYER, Gleason; RAYMOND N. NELSON, Horicon; ROBERT C. MONTGOMERY, Madison; EDWARD N. PFEFFER, Milwaukee; JOHN T. BROOKS, *Minong;* EDWIN RILEY, Park Falls; ROY F. BREEDEN, Richland Center; CLINTON C. FULLER, Stratford; CHARLES R. GOUGH, Wausau; DANIEL W. LYNCH, West Bend; JOSIAN A. POWLASS, West Depere.

To Milwaukee, Wis., to examine applicants for appointment to the Officers Reserve Corps, Major GEORGE V. I. BROWN, Milwaukee.

To New York City for orthopedic instruction, and on completion *to his proper station,* from Fort Riley, Major RALPH KAYSON, Plymouth.

Honorably discharged, Lieut. GEORGE D. SPENCER, Evansville.

Resignation of Capt. JOHN R. MINAHAN, Green Bay, accepted.

Wyoming

To Fort Riley for instruction, Capt. ARTHUR E. LANE, Laramie; Lieut. ALLAN M. GIDDINGS, Crosby.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Personal.—Dr. Cyrus T. Foster, city health commissioner of Rock Island, has been appointed commissioner of the sanitary district of Rock Island by the state board of health. Dr. Henry S. Bennett has been given a similar appointment in the Moline territory.——Dr. G. Gwin Taylor, Elkhart, has been made medical supervisor of sanitary military zones in Illinois, comprising the territory around the Rock Island Arsenal, Camp Grant, Rockford, the Great Lakes Training Station, Fort Sheridan, Scottfield, Belleville, and Chanute Fields, Rantoul.——Dr. G. Allen Lightle, Tallula, has been appointed resident medical officer of the Rock Island military district under the city board of health.

Miscellaneous.—The city authorities of Springfield , in response to a communication from Dr. C. St. Clair Drake, director of the state department of health, regarding the health organization of Springfield have agreed to take action looking to the establishment of a modern department of health, in accordance with a recommendation recently made in the report of a survey by the United States Health Service. The mayor and the commissioners of health have agreed, that if the tax levy for health purposes passes the spring election, the city will reorganize the health department, employ a full-time physician as health officer, appoint a bacteriologist and chemist, employ a full-time public health nurse, one sanitary and quarantine officer, two food and dairy inspectors and a superintendent of the isolation hospital, as well as competent help to look after the department of vital statistics.——At Mason City, March 12, Dr. Henry O. Rogier, county chairman of the Illinois Tuberculosis Association, which is a branch of the Red Cross, started a movement to organize the work of a tuberculosis commission and a number of committees were appointed to carry on the work. Dr. William H. Schuette, Mason City, has been appointed county advisor.

Chicago

Personal.—Dr. Edward K. Armstrong has been sent to France by the American Red Cross to engage in child welfare work among the civilian population.

To Address the Chemical Society.—Prof. E. V. McCollum of Johns Hopkins University, April 12, will address the

Chicago section of the American Chemical Society on "The Biological Analysis of Food."

Health Committees to be Appointed.—At a meeting of the Chicago Church Federation, March 8, action was taken to have appointed 1,000 health committees in a campaign against tuberculosis. About 2,000 sleeping porches will be built this spring, and citizens will be encouraged to sleep outdoors. The cooperation of the city health department and the Municipal Tuberculosis Sanitarium was promised in the movement.

Miscellaneous.—Suit to recover the property of the Chicago College of Medicine and Surgery, valued at $300,000, was filed, March 19, by Mrs. Neva A. Brown, widow of the late Henry B. Brown, a chief owner of the Valparaiso University. ——Under the direction of Dr. William N. Lipscomb, the first-aid car of the American Red Cross will be in Chicago during the week of April 15. Lectures will be given and classes conducted, showing modern methods of preventing railroad accidents and the administering of first aid to the injured.——At the meeting of the medical women of Illinois, March 27, an initial step was taken to raise $300,000 to equip a woman's hospital unit. Chicago's quota is $25,000, to be collected between March 26 and April 6. Dr. Clara P. Seippel was elected chairman of the finance committee. The object is to collect into one unit the women in the medical service abroad.

INDIANA

For New Hospital.—The county council at Winchester has appropriated $15,000 toward the erection of a new hospital. The county has a previous donation of $10,000 from Mrs. W. E. Miller and a lot on which to build.

Personal.—Dr. George H. McLin, Huntington, was brought home from St. Louis seriously ill. He had been traveling in the Southwest.——Dr. Andrew T. Custer, Linton, has resigned as coroner of Greene County and Dr. H. O. Woodrow has been made his successor.

Miscellaneous.—At South Bend the county council has appropriated $100,000 for the construction of new buildings for the county tuberculosis hospital.——At Decatur early in March, there were four deaths of patients from eating meat. After an investigation of the circumstances surrounding these deaths, it was decided that they were due to botulism.

For Selling Narcotics.—Dr. Benjamin F. Patton of Fontanet, formerly of Terre Haute, has been sentenced to prison for giving prescriptions for morphin. Dr. Patton was accustomed to visit a west end saloon in Terre Haute where many drug fiends gathered to get his prescriptions. He claimed he had sixty-eight patients, but the government fixed the number at 150.

New Indiana School of Medicine.—A $400,000 building for the Indiana School of Medicine is to be erected on a site just east of the Robert W. Long Hospital, Indianapolis. It is expected that the new building will be four or five stories high and built of pressed brick and stone, trimmed to harmonize with the hospital building. It is expected that $150,000 will be realized from the sale of the old building.

IOWA

Resolutions Adopted.—The Scott County Medical Society, March 5, adopted a series of resolutions calling attention to the greater prevalence of venereal disease among civilians than in the Army, and asking that future registrants for the Army be considered and dealt with in the light of an urgent war emergency and placed under military control with reference to venereal diseases. It was further resolved that delegates to the next meeting of the state medical association should be instructed to urge the state association to adopt similar resolutions.

Personal.—Dr. Mathew A. Tinley, Council Bluffs, now a lieutenant-colonel in France, has been awarded the French Cross of War.——Dr. Benjamin H. Chamberlain, Wyoming, has been made a member of the school board.——Dr. William S. Norton, Muscatine, was reelected to the board of education.——Dr. Edward S. Bowman, Davenport, county physician, has been removed from the office by the supervisors.—— Dr. Ludwig F. Guldner, Davenport, was chosen physician for the baby welfare clinic to succeed Dr. Emil O. Ficke who has entered the Army medical service.

Miscellaneous.—Through the Waterloo Tuberculosis Clinic and Dispensary it has been ascertained that there are 600 active cases of tuberculosis in Waterloo.——At Davenport a free tuberculosis clinic was opened, March 20, in charge of Dr. Roscoe P. Carney and Sidney G. Hands as examining physicians, assisted by a tuberculosis nurse.——Two new wards in the base hospital at Camp Dodge were opened, March 18, making a total of twenty-four completed wards. There are 1,500 patients in the hospital.——A number of cases of typhoid fever occurring at Dubuque led to the appointment of a committee by the Dubuque County Medical Society. After an investigation, this committee reported that there was no epidemic or general cause for alarm, but suggested certain instructions to the people of the city in an effort to avoid further dissemination of the disease.——At a meeting of the Iowa Tuberculosis Association at Des Moines, March 4, Dr. Orville W. McMichael of Chicago, the principal speaker, said that more than 500 soldiers with tuberculosis have been returned to their homes from Fort Dodge, Camp Grant, and other cantonments.——At Grinnel more than $60,000 has been raised to establish a city hospital.——At Humboldt a company has been organized to establish a hospital in the building of the old Humboldt College.——At Fort Dodge, Webster County, physicians increased their rates for professional services 50 per cent.; the new rates became effective March 15.

KENTUCKY

Meningitis.—The number of cases of meningitis at Glasgow led Governor Stanley to take action, March 12, to prevent a serious epidemic. Members of the state board of health, including the state bacteriologist, were directed to attend to the situation, and an officer of the United States Public Health Service was detailed by the Surgeon-General at Washington to work with the state authorities.

Quarantine Rules Revised.—Quarantine rules for contagious diseases recently revised by the Louisville Health Department require children who have been excluded from school because of contagious diseases or exposure thereto to have a certificate from a physician stating that the rules of the department have been complied with. Children may not return to school after the expiration of the quarantine period unless they present the certificate required.

Sterilizing Laundry.—Installation of a sterilizing plant at the armory for the purpose of eliminating all danger of contagious disease being spread through the thousands of soldiers' shirts that are delivered there and which come from thousands of homes, has been recommended to Captain Hawkins, in charge of the substation of the government depot, by Major Fricks of the United States Public Health Service, City Health Officer Baker, his assistant, Dr. R. B. Norment, Jr., and Miss Mary K. Coady, supervising nurse of the board of tuberculosis hospital.

Health Board Reorganized.—By a bill put before both houses of the legislature at its present session, the state board of health has been given jurisdiction over the bureaus of tuberculosis, hotel inspection, food and drug inspection, and vital statistics. The new board will come into existence, June 21. For the present it has been decided that it will be inadvisable to remove the headquarters of the state board from Bowling Green. Both Frankfort and Lexington have been mentioned as locations for the new board. Dr. W. L. Heiser, of the tuberculosis commission, is slated to succeed Dr. Joseph N. McCormack, chief sanitary inspector and acting secretary of the board.

Suit on New Public Health Law.—It is the plan of the present state board of health to test the constitutionality of the recently enacted law which combines the various health activities in the state. It is claimed that the title "An Act Relating to Public Health" does not sufficiently cover the subject to include the abolishment and recreation of the state board of health. The suit will be brought to prevent the governor appointing the new board in June. The law provides that if one paragraph is found invalid or unconstitutional it does not affect the rest of the bill. If that portion of the bill in question is found invalid the new law will be administered by the present board as now constituted.

Personal.—Dr. Henry E. LeCates has resigned as head of the Blue Grass Tuberculosis Sanatorium at Lexington and will go to Minnesota as a member of the state advisory tuberculosis commission, with headquarters in St. Paul.——Drs. Henry E. Tuley, David C. Morton and George A. Hendon, physicians of Louisville, have been named as members of the tuberculosis corps of the Waverly Hill Sanatorium.——Dr. Orlan T. Hughes, Stamping Ground, was elected city physician at Lexington, to fill the vacancy caused by the death of Dr. Alexander C. Brown.——The many friends of Dr. S. G. Dabney will be pleased to learn of the favorable news from his son, Lieut. William Dabney, who was wounded in an engagement in France. It is reported that he has been granted a short leave of absence and is recuperating in Nice, Italy.

MARYLAND

Personal.—Dr. George Y. Massenberg, Towson, who was with the American Red Cross in Roumania, has arrived at Moscow, Russia. He will go to France and continue to work for the Red Cross.

Mayor of Cumberland.—Dr. Thomas W. Koon was elected mayor of Cumberland for the third consecutive term at the election, March 19. Dr. Theodore A. K. Hummelshime was elected one of the four city commissioners to serve for two years. Cumberland has commission government.

Report on Pneumonia Cases.—The health department has issued a caution against contact with persons who have had pneumonia. During the past week the new cases totaled 186, compared with 152 the previous week, and 19 for the corresponding period of 1917. Sixty-one deaths from pneumonia were reported during the week.

A Special Bureau of Hygiene.—It has been recommended by Health Commissioner Blake of Baltimore, as a result of studies made by Dr. William T. Howard, Jr., assistant commissioner of health, that a bureau of child hygiene be established in the health department for the purpose of combating a high mortality rate among children.

MASSACHUSETTS

Cutter Lectures.—The Cutter lectures on preventive medicine and hygiene, were delivered by Elmer V. McCollum, professor of hygiene in the Johns Hopkins University, March 19, 20 and 21.

Officers Elected.—The annual meeting of the Massachusetts Association of Boards of Health was held at Boston, where Dr. John S. Hitchcock, Northampton, was elected president, and Dr. Francis G. Curtis, Newton, treasurer.

Medical Bequests.—By the will of Mrs. Charles H. Colburn, Milford, who died recently in Paris, a bequest of $20,000 was made to the Milford Hospital, and a fund of $100,000 to the Harvard Medical School for research in tuberculosis.

Woman Physician Honored.—Dr. Eveline C. DuBois, Springfield, sailed for France during the last week in March, to work close behind the lines in northeastern France under the auspices of the Secretariat Francais des Villages Liberes, a French-American organization, of which the legal head of the Lafayette family is the president of the committee on American relations. The Woman's Medical Society of Springfield gave a banquet in her honor and presented her with a jeweled flag pin.

Personal.—At the annual meeting of the associated boards of health of the Northeastern district of Massachusetts, Dr. George B. Fenwick, Chelsea, was elected president.——After ten years of work in Newfoundland and Labrador, Dr. John Mason Little, Jr., Boston, who was part of the time associated with Dr. Wilfred Grenfell, has returned to the states.——Dr. Eugene R. Kelley, Boston, has been appointed state commissioner of health to succeed Dr. Allan J. McLaughlin who has been called back into the federal public health service. ——At the annual meeting of the Robert B. Brigham Hospital for Incurables, Dr. Joel E. Goldtwhait, Boston, was reelected president and Dr. Francis H. Rowley, vice president.

Miscellaneous.—Eight John Harvard scholarships were awarded students of the Harvard Medical School in Boston. These scholarships are usually awarded to students who have shown excellence in their work but who do not necessarily need financial assistance.——Under the will of Rebecca A. Green, Harvard has received a donation of $10,000, $500 of which is for the purpose of founding a scholarship to be known as the John White Browne Scholarship for research in medicine.——A death from typhus fever was reported to the Boston Health Department, March 6. The patient came from Chelsea, and after several days' illness was sent to a Boston hospital where he died. The case was diagnosed by Dr. Andrew W. Sellards, Dedham, who was a member of the unit sent to Serbia to combat typhus early in the war.

MICHIGAN

Personal.—Dr. D. B. Hagerman, Ann Arbor, has been appointed local surgeon for the Michigan Central Railroad. ——Dr. Robert G. Marriner, Menominee, was seriously injured, March 7.

Miscellaneous.—Active cooperation between the military medical officers and the state authorities has resulted in the reporting of 2,000 cases of communicable diseases to the state board of health during the period from September, 1917, to March, 1918. Many of these were cases of venereal disease, and the patients were sent to hospitals to undergo treatment. Free clinics are held in Battle Creek, as well as in Detroit and other cities throughout the state.——In Detroit venereal diseases have been made reportable and power has been given the health officer to isolate persons afflicted with them. Drs. Francis Duffield, Detroit, was elected president, and Charles C. Drake, vice president of the board of health. ——After some experiences with the soldiers at Camp Taylor, Dr. Edwin R. Vander Slice, Ann Arbor, secretary of the Michigan Antituberculosis Association has returned to Ann Arbor convinced that what Michigan needs in the fight against tuberculosis is more sanatoriums, as provided for by the joint county sanatorium law passed by the last legislature. The efforts of the Michigan association for the next year will be directed toward securing city sanatoriums. The medical officers at Camp Custer have recommended a detention camp housing 2,000 men, to be composed of 250 huts, each capable of housing a squad of eight men, the whole to be enclosed with an area large enough for drill purposes. On arriving at the camp, selected men will be placed in this isolation camp.

MINNESOTA

Personal.—Dr. Jennings C. Litzenberg of the University of Minnesota has been delivering a course of lectures on sex and social hygiene, to the soldiers at Fort Snelling. The course is to continue throughout April.——Dr. Roy A. Schnacke, St. Paul, has resigned as police surgeon.——Dr. William M. Sweeney, Red Wing, had the misfortune to break his leg, early in March.

Miscellaneous.—At a public meeting in St. Paul, March 15, plans for a campaign against tuberculosis were made. The meeting was addressed by a number of the leading experts on tuberculosis in the city and state. The establishment of a tuberculosis fellowship at the University of Minnesota was proposed.——In a list of more than fifty cities St. Paul stood fourth in excellence of health conditions as reported to the Department of Commerce of the federal government in March. At Minneapolis it was reported, March 16, that there were 7,000 cases of tuberculosis in the city, over 5,000 of which were not under supervision.——At Hibbing, citizens and local authorities are cooperating with the state board of health in a campaign against quack doctors. Literature is being distributed to offset the advertising of the quacks.

MISSOURI

To Head Sanatorium.—Dr. William R. Summers, until recently assistant physician at State Hospital No. 3, Nevada, has purchased the Johnson Sanitarium at Springfield which was established by the late Dr. Samuel A. Johnson, Springfield, for the treatment of mental and nervous diseases. Dr. Johnson was killed on Nov. 26, 1917, by one of his patients who struck him on the head with an ax.

Miscellaneous.—Early in March, meningitis was slightly on the increase and an expert was employed for sixty days to help cope with the situation, on the recommendation of Dr. Eugene Carbaugh, city health commissioner.——Under the new hospital and health board, the appropriation for the salary of Dr. E. H. Trowbridge, chief school medical inspector, was cut off, and the work will be continued until June 1 under the direction of the board of education, as a private citizen has agreed to pay the salary of the chief inspector.

Personal.—Dr. W. L. Whittington, formerly superintendent of the state hospital at St. Joseph, has removed to Eldridge, Calif., where he has been made assistant superintendent of the state home for the feebleminded.——Dr. and Mrs. W. B. LaForce, St. Joseph, left, February 1, for Peking, China, where the doctor has been appointed a member of the faculty of the American Indemnity College as physician in charge. ——The state board of health has elected the following members: president, Dr. W. J. Ferguson, Sedalia; vice president, Dr. W. A. Clark, Jefferson City; secretary, Dr. George H. Jones, Jefferson City.

Social Work Conference.—Social service, made necessary because of war conditions and the reconstruction work that must be taken up in every community at the close of the war, will be the principal subjects considered at the forty-fifth National Conference of Social Work to be held in Kansas City, Iay 15 to 22. Raymond Robins, in charge of Red Cross work n Russia; Ernest P. Bicknell, director-general of the Red ross work in the United States, and Homer W. Folks, in harge of the department of civil affairs of the Red Cross n France, have important places on the program. Among the vomen speakers will be Mrs. Florence Kelley, who is one of a ommittee of three asked by the government to inspect fac- ories where soldiers' uniforms are made and to see that one are made in sweatshops, and Maude E. Minor, the only woman member of the New York State Probation Commission, and chairman of the War Department Committee on he Protection of Girls.

NEW MEXICO

Personal.—Dr. William R. Tipton has been made superintendent of the New Mexico Hospital for the Insane at East Las Vegas. Dr. Tipton was formerly medical director of the institution.——Dr. Samuel J. Crumbine, Topeka, secretary of the state board of health of Kansas, addressed the Kiwanis Club at Albuquerque on the subject of health conditions in New Mexico. He referred to the fact that there was no state department of public health in New Mexico. Dr. Crumbine's visit to New Mexico was in the interest of the enforcement of regulations regarding venereal and other communicable diseases.

For a Public Health Department.—The New Mexico Public Health Association, an organization with headquarters at Albuquerque, is making vigorous efforts to have the state authorities establish a state board of health, as well as to secure legislation for the improvement of health conditions throughout the state. The president of the association is Nathan Jaffa, Roswell. The secretary of the association has been in correspondence with the officers of national associations with reference to the study and prevention of tuberculosis, especially as it affects states like New Mexico, to which many persons with tuberculosis migrate. A new health law has been introduced into the New Mexico legislature, which, it is stated, is based on that of Indiana.

NEW YORK

Hearing on Health Insurance Bill.—A hearing was held on Senator Courtland Nicholl's health insurance bill, March 26. The bill has the unanimous endorsement of the New York State Federation of Labor, the Women's Municipal League, the Women's Trade Union League, and the Consumer's League of New York.

Personal.—Dr. Elliott T. Bush, Horseheads, has been appointed superintendent of the Chemung County Tuberculosis Hospital at Elmira. Dr. LaRue Colegrove, Elmira, has been made a member of the hospital commission.——Dr. Virgil D. Selleck has been appointed full-time health officer of Glens Falls.——Dr. Oliver W. H. Mitchell has resigned as head of the city laboratories at Syracuse. Dr. Augustus J. Gigger, formerly bacteriologist for the Rhode Island State Department of Health, has been named as his successor.

Physician Sentenced.—An authentic report states that, Jan. 10, 1918, in the United States District Court for the southern district of New York, Dr. William Llewellyn Owen was indicted on four counts and sentenced to one year on each indictment in the federal prison at Atlanta, Ga., the sentences to run concurrently. Reports state that Owen had been conducting a thriving business in the sale of various colored pills, the "miraculous powers" of which had been set forth in pamphlets circulated through the United States mails. The pills were "guaranteed to cure" all human ailments.

Better Facilities for Insane Urged.—On the recommendation of the Hospital Development Commission, the board of managers of the New York State Charities Aid Association has adopted resolutions urging more adequate facilities for the care of the insane and the feebleminded in this state. There are now two bills before the legislature providing for two new state hospitals for the insane in the metropolitan district. The measures also provide for a new state board to handle the problem of the feebleminded. The appropriation bill before the legislature calls for a total of about $2,500,000 in authorizations and appropriations to construct new buildings for the accommodation of the insane and the feebleminded.

Miscellaneous.—The Albany County Medical Society and other societies have expressed their opposition to the law making the regulations concerning narcotic drugs more stringent.——Utica has made a thorough reorganization of the city health department with new employees.——Dr. Geza Kremer for several years with the department of health of New York has been placed in charge of the Sea View Hospital and Sanitarium at Castleton Corners.——At Troy a full-time public health nurse has been employed.——A bill in the state legislature to license chiropractors is being opposed by representatives of the state department of health and the educational and medical professions throughout the state. Dr. Augustus M. Downing, deputy commissioner of education, contends that the bill is absolutely at variance with the present method of state control of similar professions, since it would take from the board of regents the power of decision in admitting candidates to practice.——The Whitney bill in the legislature, which would abolish all local boards of health, replacing them with county boards and giving complete control to the state board of health, met with so much opposition from local health authorities throughout the state that it has been withdrawn.——Strong opposition has developed to bills introduced into the New York state legislature, which if they became laws would remove all obligation on the part of rural communities to carry out physical training and health inspection. The present physical training law requires that children of 8 years or over in elementary and secondary schools should receive systematic physical training and health inspection. Among the opponents of these measures were Dr. Thomas D. Wood, professor of physical education at Columbia University, and Dr. Eugene Lyman Fiske of the Life Extension Institute, who claim that children in the rural districts need physical training and inspection more than those in the city.

New York City

Charitable Bequests.—To Harvard University for the creation of two scholarships in the medical school, $5,000, by the will of Mrs. Elizabeth C. Franham.

Gifts Wanted for Columbia War Hospital.—Base Hospital No. 1, the Columbia War Hospital, announces that it is now caring for 600 men from overseas and from the various cantonments in this country and that certain gifts will be acceptable. Among the articles particularly desired are the following: talking machines, with records; bookcases and books, games, wicker chairs, playing cards, tobacco, jellies, jams and fruits.

Personal.—Dr. Seth M. Milliken has been appointed assistant attending physician to the Roosevelt Hospital, to take the place of Dr. Kirby Dwight, who has entered military service.——Major Grayson M. P. Murphy, former head of the American Red Cross Commission in Europe, has been awarded the first Liberty Service Medal, recently created by the American Social Science Association for the recognition of notable humanitarian and patriotic services for national welfare.

Fund for Women's War Work.—March 26, the American Women's Hospitals, organized by the war service committee of the Medical Women's National Association, inaugurated a campaign to raise funds for establishing in the allied countries hospitals and clinics to be conducted entirely by American women physicians and surgeons. A woman physician in every state has been appointed by the committee to organize her colleagues for future service abroad and for immediate service in the campaign.

Resolutions Regarding Occupational Diseases.—The executive committee of the Associated Outpatient's Clinics of New York City recently adopted resolutions, in consonance with those of other medical bodies, emphasizing the desirability of the early recognition of the diseases of industrial occupation, and the necessity for detailed records of all patients, as to occupation, etc. The resolutions urge that adequate facilities be provided for the treatment of occupational diseases and industrial poisonings, and that the study of occupational diseases be stimulated among the physicians connected with dispensaries.

Miscellaneous.—The sum of $8,000 has been given by citizens to erect a building at the People's Hospital on the east side to treat children with physical defects and to conduct a campaign of hygiene.——The United States government has taken over the old Hudson Street Hospital at 67 Hudson Street, to be put into the military service.——A bill in the New York legislature provides for the establishment of a special health department and organization for Brooklyn.——A course of lectures on food and food conservation as related to the war will be given at the College of the City of New York under the direction of Dr. Charles Baskerville, professor of chemistry. The courses are open to all who are interested.

American Women Physicians Give Hospital to Serbia.—The American Women's Hospitals, of which Dr. Rosalie Slaughter Morton is chairman, in response to an official request, announces that the institution will establish a hospital in Serbia which will contain about 250 beds. This organization has already fifty workers in the war zone and has sent a motor laboratory and two ambulances to Serbia. The American Women's Hospitals is also planning to establish a chain of clinics and dispensaries throughout France and Italy manned entirely by women surgeons and laboratory assistants. Since March 25, this organization has been carrying on a campaign to raise funds for the purpose. It has organized a committee with subcommittees, whose members are conducting the campaign in each state. Fifty American women physicians are now working in France.

New York Hospitals Preparing for Soldiers.—A hearing was held, March 25, by the committee on hospital and medical facilities of the mayor's committee on national defense for the purpose of planning coordination of medical facilities in this city for the care of sick and wounded military men arriving from overseas. Dr. Sigismund S. Goldwater presided. Representatives of the United States Navy, the board of education, the immigration department, the New York State Charities Aid Association, the American Motor Car Service, the police department, the Red Cross, private hospitals and kindred institutions were present. It was pointed out that there are now numerous patients from the Navy in the public and private hospitals of this city. As a result of the conference, the state board of charities will at once order a survey of the hospital facilities of both the city and the state with the view of ascertaining their availability for military use. In all cases in which expansion of public or private hospitals is found necessary, it is the intention to make the extensions permanent. Health Commissioner Amster favored an amalgamation of the field nursing forces of the department of health with the units under the direction of the Red Cross. The Red Cross has already made preparations to meet the demands that may be made on it as a result of any great increase in the wounded military population of the city.

New York Academy of Medicine Adopts Resolutions on Occupational Diseases.—At a meeting of the New York Academy of Medicine held, March 7, 1918, resolutions in regard to the industrial disease problem were adopted urging that the authorities of medical schools be notified of the necessity of instruction in the the treatment and prevention of occupational diseases, particularly with reference to the poisonous substances used in war and other industries. It was urged that clinics be established both in New York and in the neighboring towns where there are munitions and other manufacturing plants, so that these diseases may be studied and treated in a competent manner and both employers and employees may enjoy the benefits of this knowledge and receive instructions concerning the nature of industrial hazards and how to avoid them. Large hospitals and dispensaries were urged to record accurate data concerning patients suffering from industrial diseases and to provide adequate means for their treatment. It was also urged that the importance of the early recognition of and the necessity of promptly reporting these cases be brought to the attention of practitioners, and that means be provided to extend the excellent work done by the division of industrial hygiene in the bureau of preventable diseases, of the New York City Health Department. In the resolutions, the medical press was requested to give more space to the discussion of industrial diseases, and finally, the federal government, in the interest of the conservation of health and efficiency, was requested to cooperate, through its corps of P. H. S. experts, in the supervision of conditions in factories producing war munitions and allied products.

NORTH CAROLINA

Miscellaneous.—Dr. Benjamin E. Washburn, Raleigh, in charge of county health work reports that 6,000 people at seventy-five different places heard lectures on health conditions, and that 277 hookworm patients were treated during February. Nine counties have health departments which are cooperating with the state board of health in educational, sanitary and quarantine work, the physical examination of schoolchildren, vaccinations, etc.——Arrangements have been made for free nursing service for those who are unable to pay. Two nurses have been provided.

OHIO

Fire at Milford Center.—Fire at Milford Center, March 5, destroyed a large building owned by Dr. John L. Boylan, Marysville.

State Meeting Postponed.—Because of war conditions, it has been decided by the council to postpone until October 1-3, the seventy-first annual meeting of the Ohio State Medical Association, which was to have been held in Columbus in May.

Toledo Unit in Service.—The Toledo unit, comprising the staff of the U. S. Hospital Ship *Mercy* is in active service with the Atlantic fleet. The personnel of the staff includes Surgs. Charles W. Moots and P. Bruce Brockway, and Asst. Surgs. Robert H. Butler, Bellefontaine, Marsh Dolloway and Thomas Ramsey.

Personal.—Dr. William B. Quinn, Springfield, has been placed in charge of the obstetrical department of the Springfield City Hospital, succeeding Dr. Clarence S. Ramsey, resigned.——Dr. William H. Burns, Alliance, who has been under treatment for several weeks at the sanatorium in Bluefields, W. Va., has returned home convalescent.——Dr. Ralph W. E. Cole, city epidemiologist of Akron, has resigned to become chief of the division of communicable diseases, public health, education, and vital statistics in the state health department of West Virginia.——Dr. Clayton W. Russell, Springfield, who has been under treatment at the Springfield City Hospital has returned home much improved.——Dr. Stephen U. Sivon, Ravenna, has been appointed district surgeon for the Baltimore and Ohio system.——Dr. Fernand J. Leblicq, has been appointed city physician of Sandusky to succeed Dr. John S. McClelland, who disappeared two months ago.——Dr. Chester W. Waggoner has been made city health officer of Toledo.——Dr. Oscar H. Sellenings, Columbus, who left for France several months ago is now connected with the children's bureau of the American Red Cross, Paris.——Dr. George W. Miller has been elected president of the Dayton Antituberculosis Society.

Cincinnati

Old Medical Building for Soldiers.—The old McMicken Hall has been turned over to the War Department for the housing of soldiers who are taking courses of instruction in the University of Cincinnati.

Personal.—Dr. Max C. Labermeier has been appointed temporary district physician suceeding Dr. John J. Schwartz, who resigned to enter the military service.——Dr. Adam W. Montague has been appointed receiving physician at the General Hospital.——Dr. Vera V. Norton has passed the examination for resident physician at the municipal tuberculosis sanatorium.

New Clinics.—A special medical clinic is to be established at the Cincinnati General Hospital by the medical committee for Dr. Charles L. Bonifield. This is in addition to the clinic in charge of Dr. John M. Withrow. An outdoor clinic for malignant disease is to be inaugurated at the hospital. In a plea before the board of health, March 13, Surg. Paul Preble of the United States Public Health Service, urged the establishment of a clinic to aid in the stamping out of venereal disease in the military zone in which Cincinnati is included.

Medical College Dedicated.—The new buildings of the Ohio-Miami Medical College of the University of Cincinnati were formally dedicated, March 25. Gifts of $25,000 were announced. Pres. Charles W. Dabney of the university, in his opening address, paid eloquent tribute to Dr. C. R. Holmes by whose untiring efforts these magnificent buildings were added to the university. Addresses were also made by Dr. Henry S. Pritchett of the Carnegie Foundation, Dr. Joseph Ransohoff and others. Mr. Rufus B. Smith, on the behalf of the directors, accepted the building. The chief donors were Mrs. Mary M. Emery, who gave $300,000 for the building, Dr. Benjamin K. Rachford, who gave $125,000 for the endowment of a chair of pathology, Mr. and Mrs. Charles P. Taft, Mrs. Charles Fleischmann, Col. William Cooper Proctor, Harry H. Levy, Mrs. W. T. Semple, Mrs. Christian R. Holmes, Mrs. Julian Benjamin, Miss Mary Hanna, Mrs. Emilie Heine and James P. Orr. The grand total of subscriptions was $555,000. There still remains $75,000 to be raised to free the buildings from debt.

OKLAHOMA

Personal.—Dr. Robert J. Gauldin, Oklahoma City, has resigned as a member of the city board of health. Dr. Hilbrand J. Hards, city health officer, has also handed his resignation to the mayor.

Miscellaneous.—In February at a conference between the governor, the state health officers and members of the faculty of the university and other organizations, a program for social hygiene was adopted. Governor Williams spoke of his intention of issuing a proclamation setting aside a "Hygiene Sunday," in starting the campaign.——The state board of health has issued a book of rules and regulations in regard to health matters which are to be distributed to all health officers of the state and to physicians and others who may desire it.——A tuberculosis dispensary was opened, March 12, at Oklahoma City, in charge of a public health nurse. A tuberculosis survey of the city is under consideration. Dr. Lewis J. Moorman, Oklahoma City, is to be director of the dispensary.——The commissioner of public safety at Oklahoma City has protested against the practice of small towns adjacent to Oklahoma City in sending smallpox cases to be cared for at city expense. There were eighty-four cases of smallpox in February, and ten new cases had been reported up to March 5.——At a conference of the inspectors of the state board of health under Dr. John W. Duke, Guthrie, in an effort to suppress smallpox it was decided that the state is to be divided into districts and an inspector assigned to each. Where conditions warrant, vaccination will be required of every one, and free vaccine will be distributed for the purpose.——At Muskogee, March 6, a health survey was begun.

PENNSYLVANIA

Philadelphia

Charitable Bequest.—A bequest of $1,000 to the maternity hospital of St. Vincent's is contained in the will of the late James McHugh.

Rush Hospital Fund.—The twenty-five teams of men and women engaged in a ten-day campaign to obtain $150,000 for the Rush Hospital for consumption and allied diseases, reported $25,500 as a result of the first four days.

Neurologists Needed for Service.—An urgent appeal has been received from Dr. Charles L. Dana, chairman of the National Committee for Mental Hygiene, requesting the services of neurologists and psychiatrists for the medical department of the Army without delay. Men of maturity and standing are needed for these positions.

Plans for Mosquito Campaign.—A conference was held at the Academy of Natural Sciences, March 29, in which were discussed details of a campaign begun by the federal, state and city governments, and by industrial establishments to exterminate mosquitoes in South Philadelphia and Delaware County. Dr. Benjamin F. Royer, acting state commissioner of health, presided as the commonwealth's representative and the city was represented by Dr. Andrew A. Cairns, acting chief of the bureau of health.

Smallpox Quarantine.—More than 5,000 persons, most of them colored, were vaccinated, March 27, in two city blocks after three cases of smallpox had been discovered within the area. The blocks under quarantine are from Tenth to Eleventh, and from Pine to South streets, including several small thoroughfares. The quarantine was put in force at 6 o'clock in the morning by a detail of police and 100 physicians under Dr. Henry A. Strecker aroused the residents and vaccinated them. Few offered resistance. One of the patients was found to be a sailor who is believed to have contracted the disease in a southern port and brought it to this city.

Personal.—Dr. Alice Weld Tallant, professor of obstetrics at the Women's Medical College of Pennsylvania, read a paper on "Civilian Relief Work in France" before a special meeting of the Medical Society of the Women's Hospital of Philadelphia, March 25. Dr. Tallant has recently returned from the war zone where she was connected with the Smith College Reconstruction Unit in France.——Dr. David G. Metheny of the Jefferson Medical College has been elected professor of anatomy in the medical department of Baylor University, Dallas, Texas.——Dr. Charles H. Frazier, head of the hospital unit known as the Government Head Surgery Hospital No. 11, which is equipped with 1,000 beds, has tendered his resignation to Dr. Wilmer Krusen, director of public health and charities as consulting head surgeon of the Philadelphia General Hospital in order to hold himself in readiness for service with his unit.

Medical Notes.—A joint medical meeting of the Jewish Hospital Clinical Society and the Mount Sinai Hospital Clinical Society was held at the Mercantile Club, Tuesday evening, March 26. Dr. John B. Deaver was the speaker of the evening and the meeting was followed by supper.——The Pathological Society of Philadelphia tendered a luncheon, March 29, to the American Association of Pathologists and Bacteriologists, the American and Canadian sections of the International Association of Medical Museums, the American Association of Immunologists, and the American Association for Cancer Research.——The meeting of the Philadelphia Pediatric Society and the Babies' Welfare Association will be held on Friday, April 5, at the Academy of Natural Sciences, and will be given over to the consideration of the reduction of infant mortality. The speakers will be Miss Julia Lathrop, chief of the federal children's bureau; Dr. Jessica Piexotto, of the Council of National Defense, and Dr. Richard M. Pearce of the American Red Cross. Motion pictures will show the work now being done in France.

CANADA

Canadian Tuberculous Soldiers.—Up to Dec. 31, 1917, the Canadian Hospitals Commission had cared for 2,871 tuberculous soldiers. Of that number 1,983 had been overseas, and 888 had been sent from Canadian training camps. The number of patients who had been discharged or who had died up to that date was 1,466. Of those, 803 had been overseas and 663 had not been out of Canada. Of those under treatment, December 31, 1,180 had been overseas and 225 were camp patients, making a total of 1,405 at that time.

Canadian Amputation Cases.—January 15, when complete records were available, 1,051 Canadian soldiers on whom amputations had been performed had been returned to Canada. Of that number 266 had been discharged. A classification of the amputation cases shows that 328 men have lost arms. Of these 111 have been discharged. The total number of patients who had legs amputated is 723, of whom 568 are still in the hospitals in Canada. Of the men still in hospitals, 73 lost arms below the elbow and 144 above that joint. Of the men still in hospitals who lost legs, there were 194 who had amputations performed below the knee and 374 above.

Hospital News.—It has been decided to erect in Alberta, near Calgary, a new military hospital with a capacity of 300 beds, which may be enlarged to one with a capacity of 600 to 900 beds.——Additional ward space and facilities for treatment are being provided at the military hospital in Vancouver, B. C. This will give 150 more beds.——The Manitoba Military Convalescent Hospital, Winnipeg, is to be enlarged to a 1,000 bed institution.——The capacity of the Esquimalt Military Hospital, B. C., is to be expanded from 110 beds to 300 beds.——The total accommodation of the military hospitals of Canada in contemplation is 20,366. The exact accommodation at present is 12,291, and in addition the discharge depot accommodation amounts to 2,300.——It is said that there are 20,000 wounded Canadian soldiers in England awaiting transportation to Canada. This large number will tax the accommodation of the Canadian military hospitals.

Personal.—Dr. Alfred A. Thompson, M.P., Ridgeway, who has been medical superintendent of the military hospitals of Canada, is planning to resign, as the military hospitals commission is now replaced by a civilian organization, a fact which precludes his occupancy of the position and that of member of parliament at the same time.——Dr. Harry J. Watson, Winnipeg, Manit., who has been overseas for two years as a captain in the C. A. M. C., and resigned from the Canadian army medical service, has been appointed major in the Medical Reserve Corps of the United States Army, and has left to assume his new duties. Major Watson at one time practiced in Ottumwa, Iowa, and was three years in the Philippines with the United States forces.——Major Thomas D. Archibald, Toronto, who saw service overseas, but has been commanding officer at the military hospital at Whitby, has been given command of several military hospitals in Toronto.——Lieut.-Col. D. King Smith, Toronto, who was overseas with the University of Toronto Base Hospital, served for some months in Halifax, but has now been given command of the North Toronto Military Hospital.——Col. Alexander Primrose, Toronto, who has returned to Canada from England, where he was consulting surgeon to the C.E.F., has been appointed to the command of the military section of the Toronto General Hospital, which has apportioned over 200 beds for returned soldiers.——Major Howard Lester Harris, M.B., has been invalided to England from Saloniki. He was studying in Austria when war began. Before that he was practicing in Kamloops, B. C., and enlisted at Victoria.——Dr. Wilfred T. Grenfell, C.M.G., the Labrador medical missionary, was in Toronto when he was attacked by laryngitis and ordered south by his physician. Latest advices state he has fully recovered.——Dr. Charles J. C. O. Hastings, M.O.H., Toronto, has been elected president of the American Public Health Association.——Major Gilbert Royce, Toronto, who went overseas three years ago with the University of Toronto Base Hospital, has been made a lieutenant-colonel and given command of a hospital at Bromley, England.——Dr. Percy W. Barker, Stratford, Ont., who has been in France two years, is home on leave of absence, having suffered from trench fever.——Dr. William Goldie, Toronto, will go overseas shortly for service in some of the hospitals of England.——Major Sydney S. Burnham, Toronto, who has been the recipient of the Distinguished Service Order, has been gazetted a general staff officer of the third grade. He is a son of Dr. Howard H. Burnham, Toronto.

GENERAL

The Pacific Medical College.—A letter from Dr. Charles B. Pinkham, secretary of the California State Board of Medical Examiners, states that the Pacific Medical College, Los Angeles, Calif., has never received recognition nor been approved by the California Board of Medical Examiners, that he has been informed recently that diplomas have been issued granting a degree without a requirement of specific attendance, and that a number of state boards have admitted the holders of such diplomas to examination. He asks that this information be disseminated among the state boards of the United States, since they may not have carefully investigated the record of the institution. He says that, as a result of the California board's investigation, an attorney representing the college has advised him that immediate steps are being taken to disincorporate the institution.

FOREIGN

Ichthyol Now Produced in Italy.—It has been found that the bituminous schist in the Vallepiana district in Italy yields a high grade ichthyol, equal to the best hitherto imported from Austria.

Chair of Phthisiology at Edinburgh University.—The first incumbent of the newly founded chair of phthisiology at the University of Edinburgh is Sir Robert W. Philip, professor of clinical medicine, said to be the founder of the first antituberculosis dispensary.

Fatal Gas Gangrene.—Two Italian surgeons have recently succumbed to infection acquired while operating on wounded with gas gangrene. The victims are Drs. L. di Murro and G. Sica, both of whom had been long at the front. The gas gangrene developed a few days after the infection, but there were several weeks between the two tragedies.

Exchange of Prisoners Between Italy and Austria.—The twelfth interchange of sick and disabled war prisoners recently repatriated thirty-seven Italian officers and 303 privates, but the *Policlinico* remarks that there can be no question of reciprocity, as the condition of the Austrian prisoners in Italy is so much better than that of the Italian prisoners in Austria that it is by no means an even exchange.

Italian University to be Founded in Switzerland.—The *Riforma Medica* states that Switzerland has four universities at which French is spoken and three at which German is spoken, but there is none in the Italian speaking part of the country. By a recent legacy to the canton of Ticino, and gifts from other Italians, the funds have been provided to found an Italian speaking university and steps have already been taken for its realization at Ticino.

Campaign Against Venereal Diseases.—According to a statement of Mr. Hayes Fisher, president of the Local Government Board in England, a good start has been made in the campaign against venereal diseases. In fifteen months since the regulations were issued, 135 out of 145 county and borough councils have submitted schemes, of which 112 have been approved and 111 have been actually administered. During the nine months extending to the end of September, 1917, 12,000 hitherto unknown patients were treated in the London center alone, and it was calculated that by the end of the year 1917, 16,000 would have been cared for. Manchester has established centers in all its hospitals, twenty clinics for outpatients, and a laboratory in connection with the university, where good work is being done. A circular is to be issued recommending more lying-in homes, particularly for sufferers from the disease, 75 per cent. of the expense of which is to be borne by the government.

LONDON LETTER

London, March 5, 1918.

The National Physique

In the first of a series of lectures on "Problems in British Anthropology" at the Royal Institution, Prof. Arthur Keith said that the problem of physical deterioration is an old one. When our troops returned from the South African War it was raised by the late Gen. Sir Frederick Maurice, because he found that of every five men who offered themselves as recruits, three had to be rejected because they were found physically unfit for service. Sir William Taylor, director-general of the Army Medical Service at the time, reported that of 679,703 recruits examined between 1893 and 1902, only 424,651 men were passed as fit for service by the army medical officers, while 255,022 were rejected. An army of over a quarter of a million had thus to be cast aside because it was below the military standard of the time. The consequence was that in 1903 the government of the day appointed an interdepartmental committee to inquire whether there was any clear evidence of deterioration of the national physique. That committee in 1904 recommended a systematic investigation of representive sections of the nation so as to ascertain whether or not our bodies are changing or deteriorating under modern conditions. The report was duly piegonholed, and there lies to this day covered by the dust of fourteen years. The victorious manner in which our national armies have come through conditions more severe and more trying than any to which armies of former times were ever subjected seems to allay any fear that we are not equal to our forefathers in either vigor of body or strength of will. But every country in Europe has its contingent of men unfit to bear arms and unfit for the physical brunt of civil life. Before the war Germany had to reject 16 per cent. of her young men, because bodily weakness or deformity rendered them useless as soldiers. We also have our share of the unfit; the size of that share is the index of our physical deterioration as a nation. Under present conditions the need for a physical survey of the people, instead of being merely a matter of theoretical importance, as it was at a former time, has become a matter of urgent, practical importance. The total number of our population is not the most important matter for us at present: it is the number of our fit men and women, boys and girls, that matters. The medical examinations instituted by the Ministry of National Service really constitute a physical census of our man power. Our schoolchildren also are being surveyed. Ten years ago it was wisely ordained that the board of education should carry out a medical examination of boys and girls attending schools. The need for an anthropometric survey has been urged for the past sixteen years by fellows of the Royal Anthropological Institute and has the unanimous support of all scientific men. The Conjoint Board of Scientific Societies, set up by the learned bodies and corporations of this country to place the resources of science at the disposal of the government, appointed a strong committee to prepare a scheme of survey. This committee is of the opinion that such a survey is a matter of national importance and that it can be carried out by machinery already in existence. All that is now necessary is to set up an advisory council to coordinate the work carried on by the various government departments and a bureau to deal with the statistics as they are collected.

Modern Changes in the Human Face

In his second lecture on "Problems of Human Anthropology," Prof. Arthur Keith described the discovery of the remains of a boy in Suffolk of the period which closed about 4,000 years ago, and of the skeleton of an old man who had suffered from rheumatism, dating back 3,000 years, which had been unearthed while the foundations of a flying school in the west of England were being laid. Such bones, he said, are really documents, and enable us to discover the changes that have since taken place. The face has undergone several alterations. He had taken the skulls of twenty-five men and twenty-five women of the pre-Roman period in the Royal College of Surgeons and compared them with the same number of men and women who had died in London about the end of the eighteenth century. In the modern skull the orbit is bigger; the floor seems to have sunk; the cheek bone is smaller and has been pulled backward; and the supra-orbital ridge is less pronounced. The nose has become longer, narrower and more prominent. There is also in modern skulls a marked tendency to lay down a bony "sill" at the entrance to the nose so as to narrow it. Modern palates are longer and narrower, and the teeth are arranged to form a pointed instead of a rounded arch. In regard to the lower jaw, he said that the tendency is to smooth away the sharp angle and to make the hinder border run into the lower border, while the chin is growing larger. In the ancient skull the incisors met edge to edge, but he doubted if 3 per cent. of modern persons have the old bite; though if we had to return to the method of living of four or five thousand years ago, our bones would probably go back to the ancient shape. The masseter muscle is growing less, but the temporal muscle, whose function is to crush food between the molar teeth, is increasing in size, because our modern tendency is to do hard chewing with the back teeth.

Vital Statistics in 1916

The registrar-general's return of vital statistics for 1916 England and Wales has just been published. It shows a duction of 4.5 in the marriage rate as compared with that r 1915 (when it was exceptionally high), and the lowest eath rate of children under the age of 1 year ever recorded. he difficulties of framing estimates of population owing to e war have become so formidable that it is no longer posble to put forward figures otherwise than as rough approxiations. As the estimates (except those for birth rate and arriage rate purposes) are for the civil population only, listment has been treated as equivalent to emigration. The stimated civil population of England and Wales was 4,500,000 in 1916 (15,000,000 males and 19,500,000 females). he marriages during 1916 numbered 279,846, a rate of 14.9 ersons per thousand, 0.6 below the average rate of the ecade 1901-1910. The marriage rates for 1916 were 49.5 r males and 41.0 for females, the lowest hitherto recorded r females, and the lowest but one for males. We have hus the curious phenomenon of an unprecedentedly high arriage rate in 1915 (explained in previous letters to The ournal) succeeded by an almost unprecedentedly low one 1916. The flood of marriages which set in with the second uarter of 1915 did not ebb until a year later, so that coniderably more marriages were registered in the first quarter f 1916 than in the corresponding quarter of any previous ear. These violent changes are no doubt the direct conseuences of the war, and appear in 1917 to be giving place o a less abnormal state of affairs. There was in 1916 a otable increase in the proportion of marriages of young vidows. The population of widows under 30 years of age nust have been greatly increased by the war. In proportion o the total population, the birth rate was 20.9 per thousand iving. The reduction of natality accompanying the war mounted to only 12 per cent., whereas in Germany the fall s reported to have been 40 per cent. in the two years 1915 nd 1916. The excess births over deaths was 277,303. The umber of fatal casualties incurred by English and Welsh roops during the year must be very much lower than 277,303, nd so the increase in population must have continued. The erman statistics record 1,331,000 deaths in 1916, apparently xclusive of at least the great majority of fatal war casualies, as against 1,103,000 births; and the Hungarian figures for deaths "not in action" are 428,057, as against 333,551 births. In England and Wales the deaths of 508,217 persons were registered, a rate of 13.3 per thousand. The deaths of children under 1 year of age numbered 71,646, or 91 per thousand, the lowest rate ever recorded. Eighty-eight reputed centenarians died, seventy-nine of whom were women.

PARIS LETTER

Paris, Feb. 28, 1918.

The Oculocardiac Reflex May Differentiate True Nervous Shock

At a recent meeting of the Réunion médicale de la IV-e Armée, Dr. H. Dorlencourt read a very interesting paper on this subject. Of twenty-six cases of shock in which he tested for this oculocardiac reflex, he found that it was absent in twenty. This abolition of the reflex was noted even in the milder cases of shock, and appeared to be due solely to the shock; local or general infections, the severity of the wound or hemorrhage did not seem to be factors in the suppression of the reflex. In three cases the reflex was positive, but it was weak and much retarded. In no case did it appear until after pressure had been applied to the eyeball for thirty seconds; in one case not until after 105 seconds of compression. In three other cases the reflex was inverted and retarded. These experiences suffice to prove the functional inactivity of the nerve centers regulating the vegetative processes of the body. The study of the oculocardiac reflex is thus a veritable functional interrogation of the most important centers of the *vie végétative*. It enables the physician to demonstrate that when shock is sufficiently intense, centripetal excitation becomes incapable of provoking the usual reaction on the part of these centers. The abolition of this reflex furnishes new proof in support of the theory which regards shock as being a condition of functional insufficiency of the nerve centers.

HEMORRHAGE AND PSEUDOSHOCK

Dorlencourt added that severe hemorrhage may produce a typical condition of shock; but in certain cases, relatively frequent, true shock of nervous origin does not appear. The posthemorrhagic state leads to a condition of pseudoshock, simulating true shock closely in its principal manifestations. The differential diagnosis is very difficult, but yet in all cases, the distinction should be made between pseudoshock of hemorrhagic origin and true nervous shock, because the therapeutic indications in both instances are wholly unlike. It is to be regretted that frequently the apparent identity of the symptoms determines the treatment that is adopted. To institute treatment without having differentiated between these two conditions means risking the life of the patient. Dorlencourt summarized the characteristic symptoms on which a differential diagnosis should be based, and related the experiments he has conducted to establish whether the oculocardiac reflex might serve as a differential sign. This reflex was found abolished in true nerve shock in 76 per cent. of the cases; in acute posthemorrhagic cases it was absent in only 28 per cent.

DIFFERENTIAL VALUE OF REFLEX

The examinations on which these statistics are based were too few in number to permit of drawing definite conclusions; however, it is apparent that the oculocardiac reflex is a useful sign in making a differential diagnosis between nerve shock and posthemorrhagic pseudoshock. The study of this reflex among shock victims permits of putting in evidence the state of inactivity and of functional disturbance of the centers of the *vie végétative* in the shock state. From the practical point of view this research seems, to some extent, to permit the differentiation of true shock from certain syndromes with which it might be confused.

War Wounds of the Rectum

Dr. Mocquot, professeur agrégé à la Faculté de médecine of Paris and chirurgien des hôpitaux, and Dr. Fey recently communicated to the Paris Société de chirurgie their observations made in thirty cases of projectile wounds of the rectum. Among these cases were four of wounds of the peritoneal portion of the rectum, nineteen of the extraperitoneal rectum and anus, and seven of the recto-urinary passages. Among the wounds of the peritoneal portion, there were four cases of penetrating wounds of the abdomen with multiple visceral wounds. The projectile had wounded the rectum in each case, the small intestine in three cases, the cecum in two cases, the mesentery in one case. In three cases the rectal injury had been discovered and treated in the course of a laparotomy; in one case it was not recognized. In order to expose these wounds well and suture them, the patient must be put in the Trendelenburg position, a median incision made close to the pubic bone and the pelvis well drained. Of these four patients one was in shock and died some hours after the operation; one was operated on twenty-three hours after the wounding; peritonitis had already set in and he died the next day. A third, whose rectal wound remained unrecognized and was not sutured, died on the fourth day; the fourth recovered. In this case there was, besides the rectal perforation, a perforation of the small intestine and a wound of the mesentery from which blood was spurting.

With wound of the extraperitoneal portion of the rectum and of the anus (nineteen cases), the treatment included treatment of the wounds of the soft parts and of the bony skeleton; treatment of the rectal wound and exclusion of the rectum by making an artificial anus. These wounds often being gangrenous, it is necessary to excise freely the track of the projectile—bringing the wound well into view—and extract all foreign bodies. In cases of wounds of the anal canal, it is not advisable to attempt to suture but allow the wound to heal by granulation, even at the expense of the subsequent formation of a stricture. On the other hand, wounds of the ampulla should be sutured, but always with exclusion of the rectum and the making of a colostomy. Of the nineteen patients in this group, ten were cured by operation; nine died. Mocquot and Fey had seven cases in which besides the wounds of the rectum there was also a wound of the bladder or urethra. In each case the injuries were the result of wounds inflicted in a sagittal direction (two perforating bullet wounds; four obscure wounds caused by shell fragments). The wounds of the upper rectum and bladder, four in number, all developed a rectovesical fistula. One only, seen early and treated at once, was cured by cystostomy and suture of the rectal wound. The remaining three patients, who were seen late, were infected and died even though a colostomy had been done.

Moquot and Fey state that an immediate cystostomy is the treatment of choice of rectovesical wounds. A colostomy is, perhaps, of value if there is also much injury of the surrounding soft tissues and bones. Direct suture is indicated only in wounds of the peritoneal portion of the rectum and of the bladder. These are abdominal cases, and laparotomy is effective.

Dr. Quénu, professor de clinique chirurgicale à la Faculté de médecine of Paris, stated that he had seen cases such as these only during the secondary period or late. He believes that the suture question is debatable; from his limited experience, he would be inclined not to suture but make the débridement of the rectum and anus as extensive as possible. He believes that ample excision of dead tissue in the rectum offers more protection against pelvic cellulitis and diffuse gangrene than a colostomy does. Perhaps it might be well to reserve colostomy for cases of destruction of the anus, for these lesions entail stricture, with obliteration, necessitating a colostomy, which might as well be done immediately.

Dressingless Treatment of Surgical Wounds

Dr. Phocas recently read a paper before the Paris Société de chirurgie on the complete or early dispensing with dressings in cases of surgical wounds that had healed by first intention. He has treated seventy-three surgical wounds by this method and has obtained excellent results. The procedure, which was at first utilized for the small appendectomy wound, was then used more generally. Many laparotomies done for disease of the adnexa or for fibroma have been dressed in this manner. It was found that this procedure lends itself very well to laparotomies because dressings always exert some pressure, and the patients feel better without them; gas is expelled more easily and slight distention does not cause either discomfort or pain. The absence of the dressing permits exposure of the wound to light and air, keeps it dry, and it heals more quickly. This method of procedure, the dressingless treatment, advocated some time ago by Le Fort, is made possible now because of the aseptic care given wounds during operation. It is a natural evolution of the dressing which has gone through many stages, with the method of Guérin, of Lister, of antiseptic dressings, and then the compress held in place with adhesive plaster. It is merely a case of simplifying the dressing more and more. The complete absence of dressing is the last stage of this evolution. The complications in the course of wound healing appear to occur less frequently and are of less gravity when wounds are treated by the "dressingless" method.

Honors Conferred on Americans

Acting on the recommendation of the undersecretary of state for the Service de Santé militaire, the government of the Republic has, as evidence of its appreciation of the services rendered by the American Ambulance at Neuilly-sur-Seine, conferred on three members of its Comité de direction the following decorations: M. Laurance V. Benet, president of the American Ambulance, is promoted to the grade of commander of the Legion of Honor; M. Eugène-André La Chaise, former director of the Ambulance in the army zone, is promoted to the grade of officer of the Legion of Honor; Dr. Charles Winchester du Bouchet, founder of the American Ambulance and surgeon in chief, is made chevalier of the Legion of Honor. The American Ambulance, established at the Pasteur lycée at the commencement of hostilities, was closed, July 20, 1917, handing over its quarters to the medical department of the American army. During the three years of its existence, more than 10,000 French and allied wounded were treated at the Pasteur lycée and in the auxiliary hospitals under the direction of the American Ambulance, and thousands of sick and wounded have been transported by its automobile ambulances in the army zone and in the Paris *camp retranché*.

Death of Dr. Defontaine

Dr. Defontaine, eputy and councillor-general of the *département du Nord* as just died, at the age of 59. At the beginning of the war he remained in his part of the country, which was occupied by the enemy, and suffered all the indignities inflicted by the foe. He was repatriated about a year ago, but his health having been profoundly undermined he succumbed to an affection which he had contracted during his captivity.

Personal

At its last meeting, the Académie des Sciences elected a nonresident member to take the place of the late M. Gosselet. M. Flahaut of Montpellier was elected. He has been the correspondent of the Académie for the section on botany since 1904, and is the author of many exceedingly meritorious publications, notably those dealing with the algae and with mushrooms.

Association News

THE CHICAGO SESSION

The Scientific Exhibit

The director of the Scientific Exhibit reports that many unusual and interesting exhibits are being arranged. He urges that others who may be in position to exhibit work demonstrating scientific investigation or specimens illustrating anatomic or pathologic conditions shall communicate with him. Applications for space in the Scientific Exhibit should be accompanied by a brief description and a statement of the object of the exhibit; the approximate space desired should also be stated. Allotments of space will be made in accordance with the estimated educational value of the exhibit and the priority of the application for space. Application blanks and further details are to be obtained by addressing Dr. George H. Weaver, Director of Scientific Exhibit, 637 South Wood Street, Chicago.

Special Arrangements for Medical Women

The medical women of Illinois are looking forward with pleasure to entertaining the women physicians of America in Chicago next June. Dr. Clara P. Seippel has been appointed by the Local Committee of Arrangements as the chairman of a subcommittee to have special supervision of this work. Subcommittees have been appointed to be of service to these visitors, not only during their stay, but before their arrival.

Committee on Hospitality.—Dr. Grace H. Campbell, chairman, 25 East Washington Street, Chicago, will be pleased to assist women physicians who wish hotel reservations, to obtain these so that women physicians may be lodged at one hotel.

Down town headquarters for the comfort and convenience of the women Fellows of the American Medical Association will be established in one of the women's clubs.

The subcommittee on entertainment of women physicians will be glad to hear from every medical woman who will be in Chicago during the week of the meeting and to be advised as soon as she knows definitely of the date and time of her arrival and her address while in the city, so that the committee may plan some social gatherings.

Marriages

Lieut. Alexander Boyd Montgomery, M. R. C., U. S. Army, Checotah, Okla., on duty at Camp Greene, N. C., to Miss Grace Sarah Clark of Long Beach, Calif., March 16.

Lieut. Charles Herbert Doe, M. R. C., U. S. Army, Rochester, Minn., to Miss Nora O'Donnell-Kitts of London, England, at Brighton, England, February 7.

Lieut. Harry Eugene Vander Bogart, M. R. C., U. S. Army, Chicago, to Miss Gertrude Berkey of Goshen, Ind., at Chicago, recently.

Lieut. Arnold Egard Saverien, U. S. N. R. F., Los Angeles, to Miss Dorothy Crawford of Davenport, Iowa, at Alameda, Calif., March 20.

Lieut. Kenneth Johnson, M. R. C., U. S. Army, to Miss Elsie Mathilda Ernst, both of New York, January 5.

Fred W. McKibbon, M.D., Oakdale, Calif., to Miss Mary Moorhouse of Lodi, Calif, at Los Angeles, recently.

Deaths

Major Charles B. Ewing, M.D., U. S. Army (retired), Baltimore; Missouri Medical College, St. Louis, 1879; aged 59; a Fellow of the American Medical Association; was appointed assistant surgeon in the Army, July 5, 1884; was promoted captain in 1889, and major in 1901; he was appointed a brigade surgeon of volunteers with the rank of major in June, 1898, and major and surgeon of volunteers, Nov. 1, 1899; he was retired, Nov. 17, 1909; died at his home, March 1.

William Gwain Eynon, M.D., New York City; Bellevue Hospital Medical College, New York, 1887; aged 53; a Fellow of the American Medical Association; formerly president of the Bronx County Medical Society; attending physician to the Home of Refuge, New York City; assistant attending physician to the Park Hospital, and consulting physician at the Bronx Eye and Ear Hospital; died at the New York Hospital, March 24, from pneumonia.

Sarah R. Mead, M.D., Newark, N. J.; Woman's Medical College of New York Infirmary for Women and Children, New York City, 1883; aged 70; a Fellow of the American Medical Association; a member of the New York Neurological Society; died at the Mountainside Hospital, March 17, from injuries received in an automobile accident a few hours before.

Capt. Samuel Chandler Baker, M.D., M. R. C., U. S. Army, Sumter, S. C.; University of Virginia, Department of Medicine, Charlottesville, Va., 1888; aged 51; a Fellow of the American Medical Association; a member of the American College of Surgeons; died at his home, while on a furlough from Camp Wheeler, Macon, Ga., March 20, from pneumonia.

George Francis Harris, M.D., Buffalo; Cornell University Medical College, New York City, 1904; aged 44; a Fellow of the American Medical Association; a member of the medical staff of the Buffalo State Hospital; formerly a practitioner of Binghamton; a member of the Psychiatrical Society of New York; died at his home, March 18.

Charles W. Gensimore, M.D., Bedford, Pa.; Baltimore University School of Medicine, 1898; aged 42; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; a member of the United Spanish War Veterans; died in the Western Maryland Hospital, Cumberland, March 19.

Herbert Lee, M.D., St. Joseph, Mo.; Central Medical College, St. Joseph, Mo., 1899; aged 56; a Fellow of the American Medical Association; a member of the American Medico-Psychological Association; formerly professor of chemistry in the Ensworth Medical College; committed suicide, March 21, while demented.

Lieut. George Jackson Brand, M.D., M. R. C., U. S. Army, La Fayette, Ill.; Loyola University School of Medicine, Chicago, 1910; aged 32; formerly a Fellow of the American Medical Association; a member of the Illinois State Medical Society; on duty at Fort Sill, Okla.; died, February 12, from pneumonia.

David Penfield Austin, M.D., New York City; Columbia University College of Physicians and Surgeons, 1866; aged 83; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of New York; died suddenly, March 19, following a fall in his home.

Dyer J. Jenkins, M.D., Broadway, Ohio; Starling Medical College, Columbus, 1898; aged 44; a member of the Ohio State Medical Association; formerly coroner of Union County; was instantly killed, March 19, when his acetylene lighting plant, which he was cleaning, exploded.

Archelaus Ernest Turrentine, M.D., Blytheville, Ark.; University of Nashville, Medical Department, 1903; aged 40; a Fellow of the American Medical Association; formerly a member of the Mississippi State Medical Association; died at his home, March 12, from pneumonia.

Abbott W. Slaughter, M.D., Green Bay, Wis.; St. Louis (Mo.) Medical College, 1884; aged 57; formerly a Fellow of the American Medical Association; a member of the State Medical Society of Wisconsin; died suddenly, March 18, from heart disease.

Charles Holmes, M.D., Washington, D. C.; Howard University, Medical Department, Washington, D. C., 1886; aged 67; a clerk in the office of the United States Weather Bureau for thirty-five years; died at the home of his daughter, March 13.

Lieut. Hubert Ferrell, M.D., M. R. C., U. S. Army, Tyler, Texas; University of Texas, Department of Medicine, Galveston, 1909; aged 32; a Fellow of the American Medical Association; died in Dallas, Texas, Februray 24, from spinal meningitis.

Stanley C. Newlin, M.D., Anderson, Ind.; Medical College of Ohio, Cincinnati, 1881; aged 61; formerly a Fellow of the American Medical Association; formerly president of the Madison County Medical Society; died at his home, March 20.

Percy B. Wilson, M.D., Sneads, Fla.; University of Alabama School of Medicine, Mobile, 1895; aged 46; formerly a Fellow of the American Medical Association; a member of the Florida Medical Association; died at his home, March 10.

Olin J. Fryer, M.D., Greenwich, N. Y.; New York Homeopathic Medical College, New York City, 1905; aged 44; a member of the Medical Society of the State of New York; died suddenly at his home, March 14, from heart disease.

Eugene Storer, M.D., Wilkinsburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1907; aged 33; a member of the Medical Society of the State of Pennsylvania; died at the home of his parents in Wilkinsburg, March 19.

Granville Moody Brubaker, M.D., Roxbury, Pa.; Baltimore Medical College, 1894; aged 49; formerly a member of the Medical Society of the State of Pennsylvania; died at the home of his father in Waynesboro, Pa., March 15.

Oscar James Russi, M.D., Jersey City, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1901; aged 41; formerly house physician of St. Francis College, Jersey City; died at his home, March 9, from pneumonia.

Randall Thompson, M.D., Kildeer, N. D.; Chicago College of Medicine and Surgery, 1908; aged 42; formerly a member of the Illinois State Medical Society; died in a hospital in Mandan, N. D., March 11, from acute nephritis.

William Nelson Mebane, M.D., Greensboro, N. C.; George Washington University, Department of Medicine, Washington, D. C., 1906; aged 41; a Fellow of the American Medical Association; died February 5, from pneumonia.

Benjamin F. Larue, M.D., Appleton, Minn.; Rush Medical College, Chicago, 1870; aged 71; formerly a member of the Minnesota State Medical Association; was found dead in bed, February 12, from cerebral hemorrhage.

Edgar P. Little, M.D., Manor, Ga., Atlanta Medical College, Atlanta, Ga., 1892; aged 50; formerly a member of the Medical Association of Georgia; died at a sanatorium in Valdosta, March 14, from heart disease.

Linus James McAdam, M.D., Barker, N. Y.; Niagara University, Medical Department, Buffalo, 1890; aged 59; for many years a practitioner of Buffalo; died at his home, March 17, from injuries received when kicked by a horse.

James C. Davies, M.D., Emmetsburg, Iowa; University of Iowa College of Medicine, Iowa City, 1880; formerly a member of the Iowa State Medical Society; formerly a practitioner of Idaho; died at his home, March 21.

William Edgar Wagner, M.D., New York City; Jefferson Medical College, Philadelphia, 1906; aged 40; formerly a Fellow of the American Medical Association; died at a hospital in New York City, March 17.

William H. McCurdy, M.D., Delta, Pa.; Jefferson Medical College, Philadelphia, 1881; aged 63; a member of the Medical Society of the State of Pennsylvania; died at his home, March 22, from pneumonia.

Lieut. Gustaf Lewis Norstedt, M.D., M. R. C., U. S. Army, Mount Carmel, Pa.; Jefferson Medical College, Philadelphia, 1916; aged 26; on duty at Camp Upton, N. Y.; died there, March 16, from pneumonia.

James Gilbert Hughes, M.D., Greeley, Colo.; Northwestern University Medical School, Chicago, 1892; aged 56; a Fellow of the American Medical Association; died at his home, January 4, from pneumonia.

Joseph Francis Doyle, M.D., Manchester, N. H.; University of Maryland School of Medicine, Baltimore, 1917; aged 27; an intern at St. Francis' Hospital, Hartford, Conn.; died in that institution, March 19.

Ripley H. Hunter, M.D., Bullard, Texas; University of Nashville, Medical Department, 1882; aged 49; a Fellow of the American Medical Association; died at his home, February 5, from pneumonia.

John A. Ronayne, M.D., Long Island City, N. Y.; Columbia University, College of Physicians and Surgeons, 1896; aged 44; died in the Polyclinic Hospital, New York City, March 18, from pneumonia.

James Beauregard Eubanks, M.D., Monroe, N. C.; Vanderbilt University, Nashville, Tenn., 1887; aged 56; a Fellow of the American Medical Association; died at his home, March 9, from pneumonia.

Lloyd D. Knott, M.D., Lebanon, Ky.; University of Louisville, Ky., 1866; aged 72; formerly a member of the Kentucky State Medical Association; died at his home, March 20, from an infection.

Oliver Laird Miller, M.D., Pittsburgh; Jefferson Medical College, 1863; aged 79; a Fellow of the American Medical Association; a veteran of the Civil War; died at his home, March 13.

Benjamin F. Jones, M.D., Goldfield, Colo.; College of Physicians and Surgeons, Keokuk, 1878; aged 63; a member of the Colorado State Medical Society; was found dead in his office, March 18.

Charles Gimbernat, M.D., New York City; Bellevue Hospital Medical College, New York City, 1865; aged 75; retired physician and pharmacist; died at his home, March 14, from pleurisy.

William M. Lawrence, M.D., Sandborn, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1892; aged 61; was found dead in his office, March 19, from heart disease.

William J. McGurn, M.D., Boston; Tufts College Medical School, Boston, 1904; aged 45; a Fellow of the American Medical Association; died at his home, about March 20.

John M. Yost, M.D., Pulaski, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1863; aged 80; a veteran of the Civil War; died at his home, January 7.

Charles Henry Prindle, M.D., Chicopee, Mass.; University of Vermont, College of Medicine, Burlington, 1885; aged 61; died at his home, January 21, from pneumonia.

George C. G. Givan, M.D., Harriman, Tenn.; Medical College of Indiana, Indianapolis, 1890; aged 64; a Fellow of the American Medical Association; died, March 15.

Berry Allen Watson, M.D., Columbia, Mo.; Bellevue Hospital Medical College, New York City, 1867; aged 85; died at his home, January 19, from senile debility.

William Teegarden, M.D., Springfield, Ohio; Homeopathic Hospital Medical College, 1872; aged 70; died suddenly, March 15, from cerebral hemorrhage.

Edward Lawrence Salmon, M.D., Maynard, Mass.; Harvard University Medical School, Boston, 1905; aged 40; died at his home, March 17, from pneumonia.

Charles Humphrey Treadwell, M.D., Chicago; Harvey Medical College, Chicago, 1905; aged 46; died at his home, March 24, from diabetes mellitus.

William D. McCune, M.D., Branchton, Pa.; Miami Medical College, Cincinnati, 1879; aged 70; died at his home, March 16; from senile debility.

Francis R. Salisbury, M.D., Sparta, Wis.; Rush Medical College, Chicago, 1884; aged 59; died at St. Mary's Hospital, March 20, from septicemia.

Milford B. Shipp, M.D., Salt Lake City, Utah; Jefferson Medical College, Philadelphia, 1883; aged 82; died at his home, March 15.

Mortimer Haight, M.D., Toronto, Ont.; McGill University, Faculty of Medicine, Montreal, 1893; aged 49; died at his home, March 12.

William Wesley Keeling, M.D., Nemaha, Neb.; Eclectic Medical College, Cincinnati, 1864; aged 66; died at his home, about March 19.

Joseph A. Bonnette, M.D., Baltimore; Baltimore Medical College, 1890; aged 60; died at his home, March 19, from pneumonia.

Reuben Dunn Small, M.D., Gardiner, Me.; Bowdoin Medical School, Portland, 1869; aged 80; died at the home of his son, about March 8.

Charles Frank Osman, M.D., Boston; Harvard University Medical School, 1880; aged 61; died at his home, March 9, from heart disease.

George H. Webster, Janesville, Wis. (license, Wisconsin, 1900); aged 57; died at his home, December 3, from paralysis.

Pren M. Moore, M.D., Warsaw, Ohio; Miami Medical College, Cincinnati, 1873; aged 70; died at his home, March 13.

M. H. Summers, Columbus Junction, Iowa (license, Iowa, 1887); aged 67; died at Cedar Rapids, Iowa, March 11.

Frederick J. Klussman, Toledo, Ohio (license, Ohio, 1896); died in St. Vincent's Hospital, Toledo, March 9.

The Propaganda for Reform

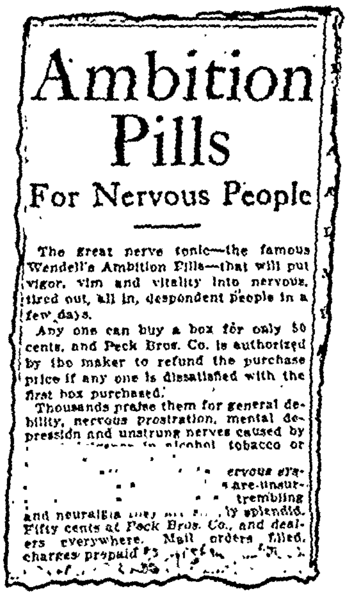
In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

SOME MISCELLANEOUS NOSTRUMS

What Was Found by the Chemists of the Louisiana State Board of Health

Louisiana has long ranked high among those southern states that have been active in safeguarding the health of their citizens. It was the Louisiana "Health Train," it will be remembered, whose "patent medicine" exhibit was responsible for suit being brought against Dr. Dowling, the president of the Louisiana State Board of Health, by one of the concerns affected by the exhibit. It may be mentioned incidentally that this suit, after a mistrial, was never again reopened. Continuing its policy of giving the public the facts regarding worthless, dangerous or misleadingly-advertised nostrums, the Bureau of Food and Drugs of the Louisiana State Board of Health has, at the suggestion of its president, analyzed several widely advertised "patent medicines." The results of some of these analyses are briefly given in what follows:

Wendell's Ambition Pills.—This "great nerve tonic" will, if one is to believe the advertisements, "put vigor, vim and vitality into nervous, tired out, all-in, despondent people in a few days." The Louisiana chemists reported that each pill was found to contain a little over one-thirtieth of a grain of strychnin and about one-fifth of a grain of iron in the form of the sesquioxid (ferric oxid). Pepper, cinnamon and ginger were also found and what was probably aloes in very small amounts. These pills are sold at 50 cents a box, each box containing forty-two pills. Under our present lax methods of permitting almost any dangerous drug to be sold indiscriminately, provided it is in the form of a "patent medicine," it seems, from the Louisiana findings, that it is possible for any one to purchase enough strychnin in a single box of Wendell's Ambition Pills to kill an adult.



Ambition Pills

For Nervous People

The great nerve tonic—the famous Wendell's Ambition Pills—that will put vigor, vim and vitality into nervous, tired out, all in, despondent people in a few days.

Any one can buy a box for only 50 cents, and Peck Bros. Co. is authorized by the maker to refund the purchase price if any one is dissatisfied with the first box purchased.

Thousands praise them for general debility, nervous prostration, mental depression and unstrung nerves caused by [illegible] alcohol tobacco or [illegible] ervous sys- [illegible] are unsur- [illegible] trembling and neuralgia [illegible] ly splendid. Fifty cents at Peck Bros. Co., and dealers everywhere. Mail orders filled, charges prepaid [illegible]

Exelento Quinine Pomade.—This preparation, which seems to be heavily advertised in the South, bids apparently for the colored trade. A typical advertisement consists of a picture of a negress with long wavy hair accompanied by the claim:

> "Kinky hair made to grow long, soft and silky by using Exelento Quinine Pomade."

Other claims, made, of course, in newspapers and not in the trade package—for the latter would subject the manufacturers to prosecution under the Food and Drugs Act—are:

> "Don't be fooled by using some fake preparation which claims to straighten your hair. Kinky hair cannot be made straight; you are just fooling yourself by using it. You have to have hair before you can straighten it. Now this Exelento Quinine Pomade is a hair grower. . . ."
>
> "Don't let some fake Kink Remover fool you. You really can't straighten your hair until it is nice and long. That's what Exelento Quinine Pomade does, removes dandruff, feeds the roots of the hair and makes it grow long, soft and silky."

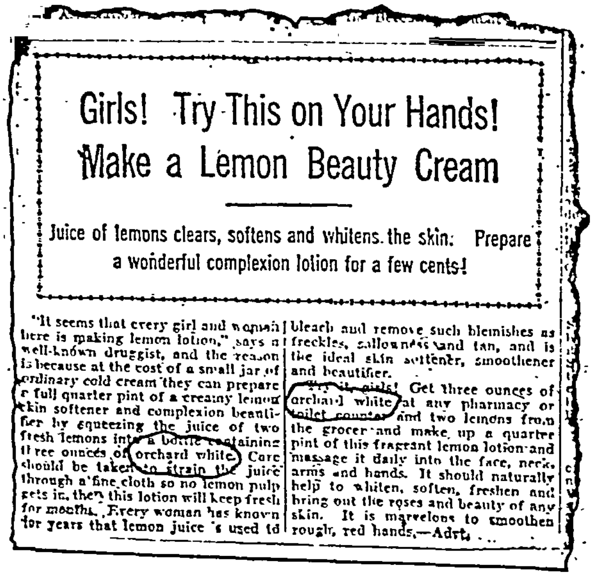
This preposterous fake was analyzed by the Louisiana state chemists who reported the following findings:

Petrolatum ("Vaseline")	91.84 per cent.
Liquid Paraffin with trace of Oil of Gaultheria	6.18 per cent.
Sulphur	1.29 per cent.
Other substances, including trace of quinin	0.098 per cent.

It would seem from these findings that calling this stuff a "Quinine Pomade" constitutes a definite misbranding under the Food and Drugs Act. Aside from this fact, however, it is a sorry commentary on the business ethics of great newspapers that they will accept the advertisement of so obvious a humbug.

Orchard White.—This is another of the thousand-and-one toilet preparations whose chief virtue lies in the money making possibilities they offer their exploiters. The advertisements of Orchard White emphasize the use of lemon juice as a "beautifier," the headline displays reading:

> "Girls! Try This on Your Hands! Make a Lemon Beauty Cream."
> "Lemon Juice Softens and Whitens Rough, Red Hands. Women can make a quarter pint of wonderful lemon beauty cream for a few cents. Nothing so good!"
> "Lemon Juice For Freckles. Girls! Make beauty lotion at home for a few cents. Try it!"
> "Lemons for Complexion. Juice of two lemons made into creamy lotion can be used to bleach, whiten and soften the skin."



Girls! Try This on Your Hands!
Make a Lemon Beauty Cream

Juice of lemons clears, softens and whitens the skin: Prepare a wonderful complexion lotion for a few cents!

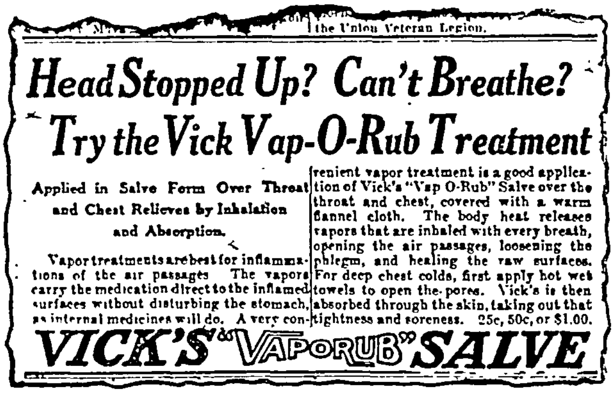
"It seems that every girl and woman here is making lemon lotion," says a well-known druggist, and the reason is because at the cost of a small jar of ordinary cold cream they can prepare a full quarter pint of a creamy lemon skin softener and complexion beautifier by squeezing the juice of two fresh lemons into a bottle containing three ounces of orchard white. Care should be taken to strain the juice through a fine cloth so no lemon pulp gets in, then this lotion will keep fresh for months. Every woman has known for years that lemon juice is used to bleach and remove such blemishes as freckles, sallowness and tan, and is the ideal skin softener, smoothener and beautifier.

Try it, girls! Get three ounces of orchard white at any pharmacy or toilet counter and two lemons from the grocer and make up a quarter pint of this fragrant lemon lotion and massage it daily into the face, neck, arms and hands. It should naturally help to whiten, soften, freshen and bring out the roses and beauty of any skin. It is marvelous to smoothen rough, red hands.—Advt.

Under such headings the advertisements advised using the juice of two lemons mixed with "3 ounces of orchard white." Throughout the advertisements the words "orchard white" are not capitalized, the obvious intent being to lead the public to believe that this "patent medicine" is an official drug. Analyzed by the state chemists of Louisiana, "Orchard White" was reported to be nothing more mysterious than a mucilage containing bismuth citrate, boric acid, alcohol and gum tragacanth. In commenting on this product, Dr. Dowling said: "Claims in the advertising, in addition to being very much exaggerated, are also false and misleading. The advertising of this preparation, to my mind, is particularly objectionable for the reason that it exploits a simple and harmless article—the juice of lemons—in order to lead the unsuspecting to purchase a product which might prove harmful."

Derwillo.—This is a nostrum sold for the skin and complexion and put out by "Mae Edna Wilder, Inc., of Rochester, N. Y.," one of the numerous names under which the Neal-Adkin mail-order concerns advertised. The state analyst of Louisiana reported that the preparation consisted of zinc oxid, calcium carbonate, starch and salicylic acid in water, the whole thing colored with carmine and perfumed with odor of rose or rose geranium.

Vick's Vap-O-Rub.—This product is a simple salve, and in general, the advertising is more conservative than is common to products of this type. The Louisiana chemists reported that Vaporub appears to be a mixture of yellow vaseline, which comprises more than three fourths of the salve, the remainder consisting of camphor, menthol and oils of thyme, eucalyptus and turpentine.



the Union Veteran Legion.

Head Stopped Up? Can't Breathe?
Try the Vick Vap-O-Rub Treatment

Applied in Salve Form Over Throat and Chest Relieves by Inhalation and Absorption.

Vapor treatments are best for inflammations of the air passages. The vapors carry the medication direct to the inflamed surfaces without disturbing the stomach, as internal medicines will do. A very convenient vapor treatment is a good application of Vick's "Vap O-Rub" Salve over the throat and chest, covered with a warm flannel cloth. The body heat releases vapors that are inhaled with every breath, opening the air passages, loosening the phlegm, and healing the raw surfaces. For deep chest colds, first apply hot wet towels to open the pores. Vick's is then absorbed through the skin, taking out that tightness and soreness. 25c, 50c, or $1.00.

VICK'S "VAPORUB" SALVE

La Creole Hair Dressing.—We are told in an advertisement in the Roanoke (Va.) *World-News* of Feb. 25, 1918, that "La Creole Hair Dressing Restores Original Color to Your Gray Hair." Further, we are asked to believe that this preparation is "No Dye" and does its work because it "Revives Color Glands." To quote:

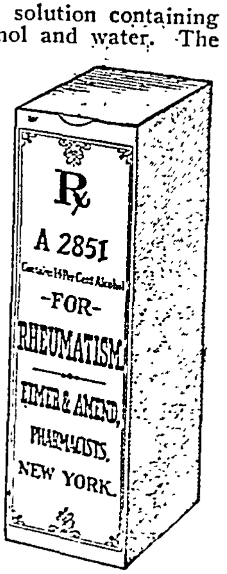
> "La Creole revives the natural color glands. In a short time you will be delighted to see all your gray hair (and entire head of hair) turn to the natural lustrous dark color your hair used to be. Not even a trace of gray will show—but all your hair will be of an evenly dark shade."
> ". . . get the original Hair Color Restorer—La Creole."

While in the newspaper advertisements "La Creole" is still a "hair restorer," on the trade package it is a "hair dressing." It used to be a "hair restorer" on the trade package but the manufacturers now blandly announce that "to comply with the Pure Food and Drugs Act the name was changed from 'restorer' to 'dressing' . . ." Lying on the trade package is, since the Food and Drugs Act went into effect, likely to prove expensive; lying in newspaper advertisements is still safe and, therefore, in keeping with the ethics of the "patent medicine" business. La Creole was analyzed by the Louisiana chemists who reported:

"This product consists of a perfumed solution containing lead acetate, sulphur and glycerin, alcohol and water. The action of the lead acetate and sulphur forms a lead sulphid compound which is dark brown thus giving hair a dark brown color."

From this it will be seen that La Creole, in addition to being advertised under lying claims, is one of those dangerous lead-containing mixtures whose use may give rise to symptoms of poisoning.

Prescription A 2851 for Rheumatism.—This product, which is said to have been known earlier as "Eimer and Amend's Rheumatic Remedy," was analyzed by the state chemists of Louisiana who reported that the preparation seemed to be essentially nothing more nor less than a low grade of sherry wine containing approximately 7½ per cent. of potassium iodid.



Sloan's Liniment.—This preparation is one of those proprietary remedies which, if truthfully advertised, might have a very proper place among home remedies. Unfortunately, it

Mississippi October Examination

Dr. W. S. Leathers, secretary of the Mississippi State Board of Health, reports the written examination held at Jackson, Oct. 23-24, 1917. The examination covered 8 subjects and included 64 questions. An average of 75 per cent. was required to pass. Of the 11 candidates examined, 8 passed and 3 failed. Four candidates were licensed through reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Birmingham Medical College	(1915)	81.2, 81.5
Chicago College of Medicine and Surgery	(1917)	77.5, 80
Loyola University	(1917)	83

Journal Revi

Book Notices

Shock at the Front. By William Townsend Porter. Cloth. Price, $1.25. Pp. 151. Boston: The Atlantic Monthly Press, 1918.

Much of the material in this book originally appeared a series of articles in the *Atlantic Monthly;* hence the mary purpose of the author was to write an informative entertaining rather than a scientific article. The autho writes in colloquial style with a conspicuous sense of hu and his book is full of vivid descriptions of scenes en route and at the front.

Unfortunately, the promises held out by the author in the beginning of the book that he had discovered and would explain the cause of shock are not fulfilled. In concluding he says:

> I sailed for my own country, bearing with me the certainty that fat embolism is a frequent, if not the most frequent, cause of shock as seen on the battle field; and the further certainty that the use of carbon dioxid respiration treatment is of advantage.

The theory which he attempted to prove was that shock is always accompanied by low blood pressure; is caused by fat embolism in the capillary circulation; occurs most frequently, if not altogether, in cases of fracture of long bones, or in cases of extensive wounds of the subcutaneous fat tissues; the embolism causes a blocking of the vessels with a bleeding of the arteries into the veins, and the rebreathing of expired air changes the respiration, elevates the blood pressure and overcomes the shock. The details of his experiments are necessarily merely fragmentary outlines, but are probably more than sufficient for lay readers. It probably makes very little difference to the lay reader whether shock is produced, as suggested by Dr. Porter, or whether many other factors, such as those considered by the Medical Research Committee, whose extensive studies were recently published in The Journal, are of greater importance.

It is unfortunate also that the author sometimes paints with too heavy a brush. This is particularly true of the fourth chapter describing his visit to Compiègne and his observations of the Carrel-Dakin method, concerning which he is more than optimistic. The lay reader is likely to expect too much after reading the following description of an illustrative case seen after Dr. Porter's return:

> I saw recently in New York a man who had had for twenty-five years a large ulcer on the leg. He entered the war hospital of the Rockefeller Institute, July first. His wound was measured and the theoretical curve was drawn. It was seen that the curve would strike the normal at August 6. "On August 6," the man was told, "you will be healed"; and on the promised day, the last square centimeter closed.

But these considerations should not detract too much from the graphic pictures drawn by the author, and from the entertaining qualities of his book.

A Text-Book on Gonorrhea and Its Complications. By Dr. George Luys, Chief Medical Officer of the Urological Centre at the Military Hospital, Versailles. Translated and edited by Arthur Foerster, Captain, R. A. M. C. (T. C.). Second revised edition. Cloth. Price, $6.

In his preface to the second English edition, Capt. Arthur Foerster states that both Dr. Luys and he have been away from their homes for many months, and that collaboration being impossible, only a few minor changes have been introduced into the second edition. He points out further that no radical advance in the knowledge and treatment of gonorrhea has been made during the last few years. Most important among the alterations is the substitution of new figures for figures showing instruments of German manufacture. The colloidal silver preparations are especially more strongly advocated, and some remarks on electrical treatment have been added. The work is an excellent and complete discussion of the subject.

Medicolegal

Liability of Private Hospital for Theft by Nurse and Attack

(Vannah vs. Hart Private Hospital (*Mass.*), *117 N. E. R. 328)*

The Supreme Judicial Court of Massachusetts sustains exception to a verdict for the defendant, which it was sought to hold liable for an alleged theft by a nurse of a ring which the plaintiff wore when she went under the ether for an operation, and missed when she regained consciousness in the private hospital operated by the defendant for gain. The court says that on the evidence the jury was warranted in finding that the ring was forcibly removed from the plaintiff's hand by one of the operating nurses who, when last heard from, was in California. If the nurse did steal the ring, it was plain that the defendant was not liable on the ground that in stealing the ring the nurse was acting within the scope of her employment as a servant of the defendant. If the plaintiff had stood in the relation of a stranger to the defendant, there would have been no error in the trial; but she did not stand in such relation. The case was not tried on the footing that the rights of the plaintiff in this action depended on the contract made by her with the defendant, and the presiding judge was wrong in telling the jury that the defendant's liability depended on the plaintiff's proving that it was negligent.

Under the contract entered into by the defendant corporation, it was its duty not only (1) to give the plaintiff a room in the hospital before and after the operation, and (2) to give her surgeon and family physician the use of the operating room for the operation, but also (3) to give to the plaintiff the services of such nurses as were necessary for her care before, after and during the operation. It expressly appeared that she paid to the hospital $15 a week for attendance. The services of the nurses which, under the contract, the defendant was bound to furnish her included the services of nurses while she was unconscious from the effects of the ether, a condition which was a necessary part of the operation; and the question which this court had to decide was whether there was a violation of duty on the part of the defendant under this contract if the operating nurse in question stole the ring by forcibly pulling it off the plaintiff's finger while she was under the effects of the ether, or whether on the facts appearing at the trial the jury could have so found. The court is of the opinion that the jury could have so found.

If, for example, a stranger had burst into the operating room, attacked the plaintiff and done her bodily harm, or had attacked the plaintiff while the nurses were carrying her from the operating room to her own room, and the defendant's nurses had stood by and done nothing to protect the plaintiff from those attacks, it is plain in the court's opinion that there would have been a violation of the duty owed by the defendant under its contract with the plaintiff. It is equally plain, in the court's opinion, that the duty owed by the defendant under its contract with the plaintiff extended to the care of the rings on her fingers while she was unconscious from the effects of the ether, as well as to the security of her person. And, finally, it is equally plain in the court's opinion that there is as much a violation of the duty owed by the defendant under the contract when the attack on the person or larceny of the ring is committed by one of the defendant's own nurses (whose duty it was to protect the plaintiff), as well as in the case in which the attack is made by a stranger, and the nurses do not undertake to protect her from the attack.

In its legal aspects, the case is governed by the decision in *Bryant* v. *Rich*, 106 Mass. 180, wherein it was held that, as a matter of contract, a passenger on a steamer had the right to receive proper treatment from the defendants and their servants and all of them. But a defense was made out if the defendant's evidence was believed that when the plaintiff was received into the hospital she was asked to put into the custody of the defendant corporation all her "valuables." On the other hand, if the plaintiff's evidence, that she was asked only to put her money into the custody of the hospital, was believed, her rights depended on the rule of *Bryant* v. *Rich.*

Communication of Syphilis to Wife an Assault

(State vs. Lankford (*Del.*), *102 Atl. R. 63)*

The Court of General Sessions of Delaware holds, as the jury was charged in this case, that a husband may commit an assault and battery on his wife, notwithstanding the marriage relation. A wife in confiding her person to her husband does not consent to cruel treatment, or to infection with a loathsome disease. A husband, therefore, knowing that he has such a disease, and concealing the fact from his wife, by accepting her consent, and communicating the infection to her, inflicts on her physical abuse, and injury, resulting in great bodily harm; and he becomes, notwithstanding his marital rights, guilty of an assault, and indeed, a completed battery. If the accused knew he was infected with syphilis, and his infection was unknown to his wife, the intent to communicate the disease to her by having sexual intercourse with her may be inferred from the actual results. If the jury should find the evidence that the accused, knowing that he was infected with a venereal disease, and, without informing his wife of the fact, had sexual intercourse with her after such knowledge had been communicated to him, and thereby infected her with the disease, their verdict should be guilty. If the jury should find that the accused, during the period he had sexual relations with his wife, did not know that he was infected with a venereal disease, and that he did not communicate with his wife after being informed that he was infected, their verdict should be not guilty. The verdict was guilty.

Typhoid Fever Not Caused by an Accident

(State ex rel. Faribault Woolen Mills Co. et al. vs. District Court, Rice County, et al. (*Minn.*), *164 N. W. R. 810)*

The Supreme Court of Minnesota reverses a judgment which allowed compensation under the workmen's compensation act to an employee of the woolen mills company for temporary disability caused by typhoid fever, the germs of which were alleged to have been ingested by drinking infected water furnished in the company's factory for the use of its employees. The court says that if contracting this disease by drinking infected water was an accident within the definition thereof contained in the law, the evidence was probably sufficient to sustain the findings of the district court.

Under statutes which provided compensation for personal injury by accident without defining the meaning of the terms used, there was a diversity of opinion among the courts as to whether diseases, and especially the so-called "occupational diseases," were accidents within the meaning of the statute. The American statutes seem to have been framed largely along the lines of the prior English statute. The English courts held that a disease, unless contracted in consequence of some injury to the physical structure of the body, was not a "personal injury by accident," within the meaning of the English law, until by amendment the law was expressly made to include occupational diseases. In *Finday* v. *Tullamore Union*, 48 Ir. L. T. 110, 7 B. W. C. C. 973, it was held that typhoid fever was not an accident within the meaning of the law. The courts of Michigan, New Jersey and Ohio seem to have taken the same view as the English courts. The Massachusetts court distinguished their statute from the English statute on the ground that it omitted the element of accident as a condition to recovery, and held that contracting a disease was "a personal injury," although it might not be an accident. The Wisconsin court held that contracting typhoid fever was an accident within the meaning of their law, but forceful reasons for the opposing view are set forth in the dissenting opinion of Justice Barnes. The United States Circuit Court of Appeals for the Ninth Circuit held that contracting typhoid fever was an accident within the terms of an insurance policy indemnifying against claims "on account of bodily injuries accidentally suffered."

Gowers, that they are vascular disorders. Allbutt's view of the nature of angina is this: that the angina of Heberden is a pain located in the ascending artery, or in the suprasigmoid portion of the ascending aorta, and that this pain is due to tension or stretching of the fibrous coat, the adventitia. Since, he says, pacinian corpuscles have been demonstrated in the fibrous coat of the artery, in this respect the pain is like the pain of intestinal colic, or any pain caused by stretching of the fibrous investment of some abdominal structure or dragging or pulling on the omentum. He believes the cause of this pain is an aortitis which may be a chronic, a subacute or an acute aortitis, or may be a chronic aortitis with acute exacerbations. He regards as the proximal causes of this aortitis the usual factors which are more or less definitely recognized in the causation of senile atheroma of the aorta or of the arteries, but especially three influences—syphilis, influenza and rheumatism. In substantiation of this view he cites almost innumerable cases illustrating the causes of angina in comparatively young people, in whom syphilis would cause aortitis. He also cites cases in young people, even in children, in the course of acute rheumatism, and one or two cases in which necropsy revealed that there was an acute aortitis in these children in addition to rheumatic infection of the heart muscle or valves.

Now he says he cannot attempt to discuss all of the eighty hypotheses of angina that Huchard had collected, but discusses the principal one, namely, coronary disease and cramp of the coronaries, spasm of the heart muscle, distention of the heart muscle, etc. In discussing coronary disease he calls attention to the fact that one might say the majority of old people show more or less coronary sclerosis after death, and yet the majority of such people never suffer from angina. On the other hand, he cites many cases of people who die, having suffered from typical angina, in whom the coronaries were not diseased at all—disease could not be found. He criticizes clinicians and pathologists alike for not investigating carefully the condition of the adventitia of the artery, saying that they usually content themselves with the statement that the aorta shows more or less sclerosis, and in syphilis they study the intima and media, but rarely, if ever, the outer coat of the artery. He doubts that the heart muscle itself is capable of pain, because the ganglions and nerves of the heart, he believes, are motor rather than sensory; nevertheless, when disease of the heart does produce pain, he thinks the pain is caused by tension of the fibrous investment of the structures of the heart. He admits that pain occurs in coronary thrombosis or coronary occlusion, believing that when pain, as Dr. Herrick has said, occurs as the result of coronary occlusion it is the result of sudden blockage; and he quotes Kaufmann that it is only sudden occlusion of a main coronary artery which produces pain. Nevertheless, he believes that the pain of sudden blockage of the coronary artery from embolism, for instance, can be distinguished, and is to be distinguished, from typical Heberden's angina, and he gives exactly the symptoms which Dr. Herrick has mentioned, not only that the pain is frequently pericardial or epigastric, but that there are certain other associated symptoms which do not properly belong to Heberden's angina, namely, dyspnea, disorders of the pulse, as Dr. Herrick has said, failing circulation, failing heart and lowering blood pressure; whereas in typical angina the pulse is rarely altered to any appreciable extent. It may be slowed a little, or increased a few beats. The blood pressure, however, is variable. In some cases it may fall; in others it remains unaltered, while in others it rises, and he cites various observations from such observers as Mackenzie that there is nothing constant in the blood pressure during angina, for it certainly does not always fall, nor are there always symptoms of collapse, edema of the lungs, vomiting, etc., as in coronary embolism. He would regard such symptoms, if they occurred, as epiphenomena and due to associated lesion. He believes the sudden death in Heberden's angina is due to inhibition, and that it is a manifestation of the impression made on the vagus by the pain. If an attack of gallstone colic can produce pain by inhibition, as he witnessed in one young woman whose heart showed absolutely no disease, then how much more easily may a diseased heart be stopped through the influence of pain on the vagus. In further corroboration of his theory he cites the pain of pericarditis, but gives cases showing that when angina has been present in cases of pericarditis that have come to necropsy sooner or later, the changes of pericarditis were found at the root of the aorta where the pericardium is reflected over the roots of the aorta. And this reminds me of the statement of Dr. LeCount that in case, as he says, the circulation at the roots of the aorta is provided by the anastomoses with other vessels, may not that very change in the coronary vessels in this situation lead to changes in the outer or fibrous coat of the aorta, which changes themselves may be responsible for the angina? I am not here to defend Allbutt's view, although I will say it appears to me as a hypothesis likely to explain the diversity of findings which are recorded, and the reason why so many investigators have such very different views concerning the nature and cause of the pain.

Allbutt rejects the theory of the angina's being due to distention of the heart muscle, citing the statements of the late John H. Musser and other authors to the effect that they had recognized cases of typical angina in which the angina totally disappeared after dilatation set in and mitral insufficiently became established, and reappeared with the return of compensatory hypertrophy. I think Allbutt would assume that in such cases the dilatation lessens somewhat the strain brought on the suprasigmoid portion of the aorta and therefore does away with such tension and stretching of the sensitive coat of this portion of the vessel as to bring about angina. He believes the theory of spasm of the heart muscle is not tenable, since, as he asks, What is systole but transient spasm of the heart muscle? Spasm of the coronaries and intermittent claudication he looks on as makeshift views to explain the great variety in the morbid anatomic changes found in the hearts to which I have alluded. In some hearts suffering with angina the coronaries were not diseased, and in others they were greatly diseased. On the whole, Allbutt, it seems to me, has presented a very strong case, and whether it answers to all cases or not, it certainly does seem to me that his views explain the overwhelming majority of cases, both in their causation and in their symptomatology, and we may say also in those measures which relieve angina.

8. **Intestinal Intoxication in Infants.**—Investigation of cases of intestinal intoxication by Schloss has furnished evidence which emphasizes the importance of the loss of fluid and the impaired secretion of urine. Determinations were made on thirty normal infants and on forty-six patients with intestinal intoxication. Thirty-six had acidosis and thirty-three of these showed an increase in the nonprotein nitrogen of the blood. There were, therefore, only three patients with acidosis without an increase of the nonprotein nitrogen. It is therefore apparent that infants suffering from intestinal intoxication show a marked increase of nonprotein nitrogen and urea in the blood. This increase is not due directly to increased concentration of the blood from loss of water, but to defective kidney elimination.

The renal lesions in intestinal intoxication are not sufficient to account for the impaired elimination by the kidney. It is probably due to the fact that lack of water restricts the formation of urine. This condition is probably due to the following factors which may act singly or in combination: 1. The loss of water in the stools is so great that it is impossible for the infant to ingest sufficient fluid to replace the loss. 2. The patient refuses to ingest fluid or vomits practically all that is taken. As a result the tissues become dehydrated. The retention of nitrogenous waste products and the failure of the kidney to do its part in preserving the acid-base equilibrium results from the deficient secretion of urine. The oliguria may be due to the fact that the dehydrated tissues hold as much water as possible so that none is available for the formation of urine. Other factors, dependent mainly on the loss of water, which may play a rôle are: (1) an increase in the concentration of blood colloids to such degree that their osmotic pressure is greater than the arterial pressure in the kidney; (2) a diminution in the total blood volume leading to decreased blood flow through the kidney. The symptoms of intestinal intoxication are essentially those of uremia. The two conditions are similar in all essentials. In one, defective kidney function is due to an organic lesion; in the other it results from the negative water balance and consequent oliguria. Acidosis plays a definite part in the symptomatology of intestinal intoxication, but the essential cause is probably some unknown toxic agency.

23 Asthma Considered in Its Relationship to Vegetative Nervous System. F. M. Pottenger, Monrovia, Calif.—p. 417.

12. **Pathologic Uterus at Menopause.**—Analyzing a series of cases in which he performed hysterectomy, Robins found that 58 occurred in women who were 40 years old and over, and in all of these the complete removal of the uterus and adnexa had been practiced. In 28 of these the operation was performed for fibroids, pelvic inflammation and other conditions in which the impossibility of conserving the organs was manifest and beyond dispute. In the remaining 30, cancer was either a positive or a possible diagnosis. In 4 a positive diagnosis of cancer of the cervix, afterward confirmed by the microscope, was made and a Wertheim operation, preceded by cauterization with the Percy cautery, was done. In 26 a diagnosis of chronic metritis, including in this, induration of the cervix, was made and a possibility of malignancy considered. In practically all of these bleeding from the uterus was a prominent symptom, manifesting itself as irregular or continuous bleeding, and sometimes accompanied by marked anemia. In 2, cancer of the fundus was found on opening up the uterus.

13. **Exudate in Pneumonia of Typhoid.**—In the exudation in lobar pneumonia accompanying typhoid the mononuclear cells predominate. These mononuclear cells are classified by Forman and Hugger as: (1) lymphoid cells; (2) epithelial cells which have desquamated into the air sac; (3) large mononuclear leukocytes in abundance which contain indophenol oxydase granules; (4) large mononuclear leukocytes which are not so numerous and which do not contain the granules reacting to the indophenol blue synthesis.

14. Abstracted in The Journal, April 28, 1917, p. 1287.

15. **Spiral Fractures of Tibia.**—Davison urges the treatment of spiral fractures of the tibia by external reduction and external immobilization which, he says, usually results in imperfect union of the fragments with defective function of the leg. Treatment by open operation and autoplastic repair usually results in early good anatomic union of the fragments with restoration of the strength and function of the leg. The autoplastic transplantation of bone in the repair of a recent spiral fracture of the tibia is a capital operation, which requires careful technic, capable assistants and aseptic surroundings.

17. **Digitalis in Control of Auricular Fibrillation.**—With proper precautions Halsey believes that the following conclusions can be drawn: The gross irregularity of the ventricle in cases with fibrillation of the auricle can be controlled by digitalis if sufficient drug is administered. The patient should be instructed to continue the use of digitalis for the remainder of life, and should be taught how to determine the amount of the dose necessary from day to day to control the heart rate. Give sufficient drug to maintain the rate of the ventricle below 70 per minute when counted after a rest in the late afternoon. The fibrillating auricle under a short course of digitalis may return to normal rhythm. In auricular flutter the aim of treatment with digitalis is to produce auricular fibrillation and then control the rate of the ventricle with digitalis, hoping in the favorable cases for a renewal of normal sequential rhythm.

29. **Functional and Anatomic Findings in Renal Disease.**—A group of thirty cases of renal disease have been studied by Stengel and his associates by certain of the recently introduced methods of renal functional testing, including the estimation of the plasma chlorids. Fifteen of these cases have come to necropsy, thus affording an opportunity of comparing the functional and anatomic findings. The cases of acute nephritis showed rather a pronounced impairment of all the renal functional tests. The cases of advanced chronic glomerulonephritis showed, in the most pronounced degree, elevation of blood pressure, depression of phenolsulphonephthalein excretion, elevation of blood urea of nonprotein blood nitrogen, fixation of urinary specific gravity and the presence of albuminuric retinitis. These cases were characterized, however, by a normal or even a definitely subnormal plasma chlorid level, and by a considerable reduction of the plasma bicarbonates. Those cases which exhibited marked tendency to proliferative changes in the glomerular tufts were characterized, as a rule, by higher blood pressure than the cases which exhibited chiefly hyaline changes in the tufts. The cases which might have been classed clinically as chronic parenchymatous nephritis or as nephroses, because of the very slight elevation of blood pressure, the less marked depression of phenolsulphonephthalein, the less marked elevation of nonprotein nitrogen and the more nearly normal urinary specific gravity, and because they exhibited conspicuous edema, especially of the face, and abundant albumin and casts of all kinds in the urine—these cases were less definitely characterized histologically than had been expected. While they showed pronounced degenerative or necrotic changes in the tubular epithelium, they also showed conspicuous, even advanced glomerulonephritis. Histologically, their separation from the clinical group of advanced glomerulonephritis would have been difficult, perhaps impossible. Grossly, the kidneys in these cases were identical with those of the other group just mentioned. The plasma chlorids were elevated in the two cases of this group studied in this connection. The cases which clinically and histologically were cases of renal arteriosclerosis, exhibited a variety of forms of kidney, grossly, and could not have been properly classified on gross appearance alone. The blood pressure, and especially the pulse pressure, although much above normal, were usually lower than in cases of advanced glomerulonephritis. The plasma chlorids and plasma bicarbonates were normal or approximately so. In all cases with elevation of blood pressure some fall of pressure was noted in the last five or ten days before death. Contrary to expectation, however, the fall in diastolic pressure was closely proportional to the fall in systolic pressure, and not less, as would have been expected.

30. **Relationship of Idiopathic Cardiopathy and Goiter.**—The symptomatology of the condition described by clinicians as thyrotoxic cardiopathy, Symmers says, is identical with the symptomatology of the lesion familiarly known among pathologic anatomists as idiopathic dilatation and hypertrophy of the heart. The clinical features are characterized by signs of great increase in the size of the heart, with or without murmurs of relative insufficiency and with or without signs of decompensation, as shown by dyspnea, subcutaneous edema, transudation in the serous cavities, cyanosis and the like, by tachycardia, and, on occasions, by bilateral exophthalmos with or without detectable indications of enlargement of the thyroid. Thus the symptoms are largely those of the cardiopathy, and signs of thyroid disturbance, such as tachycardia, tremor, exophthalmos and enlargement of the thyroid, if present, are apt to be projected into the background rather than to assume a prominent place in the picture. Of these symptoms, the tachycardia is constant, and with the patient in bed and at rest, varies between 90 and 160 beats to the minute. Anatomically, the so-called thyrotoxic cardiopathy is characterized by great enlargement of the heart, due to dilatation and hypertrophy of all the chambers or of different combinations of chambers without valvular or pericardial, arterial, renal, pulmonary or other of the causes customarily invoked to explain enlargement of the heart. The so-called thyrotoxic cardiopathy is associated with definite structural alterations in the thyroid in the form of moderate changes in the size of the gland, overgrowth of the fibrous trabeculae, rearrangement of the architecture of the parenchyma, dependent on redistribution of the stroma, regeneration of vesicles and dilatation of the older alveoli, and variations in the amount and staining reaction of the colloid—a chronic interstitial and hyperplastic thyroiditis.

31. **Effect of Diuretics on Blood Pressure.**—Experiments were undertaken by Bridgman and Hirose in the hope of affording further light on the tenability of Traube's theory under conditions of increased functional demand on the kidney. It was thought possible that, if the renal artery were narrowed, but not occluded, and then diuretic substances administered intravenously, the compensatory nature of hypertension might be revealed. Narrowing of the renal artery without obliteration was made possible by the aluminum band of Halsted. The results of these experiments were negative. They give no support to the view that hypertension in chronic renal disease is a compensatory mechanism, brought into play when the renal arterial stream-bed is narrowed, by chemical or reflex paths, to counteract the effect on excretion of the locally diminished blood flow. Their value is only that of negative evidence in general. They do not disprove the compensatory nature of hypertension, but show that its demonstration is not to be had by the experimental method employed.

32. **Gastric Secretion During Fever.**—In a series of five experiments on two dogs in which fever was produced by nucleate and prodigiosus, and in twelve experiments on five dogs, in which a temperature elevation as high as from 105 to 112 was caused by external heat, the changes produced in the secretion caused by the injection of 1 c.c. of gastrin were striking and uniform. The volume was diminished; at times there was no secretion at all. The total and free acid were reduced. The chlorids were practically constant. The authors are of the opinion that these experiments prove that during fever produced by the injection of sodium nucleate or *B. prodigiosus*, or during temperature elevation caused by external heat, gastrin is unable to induce the normal secretion of gastric juice. The changes in the gastrin secretion are exactly the same as those found in the gastric juice secreted in response to food during fever. It is suggested that during fever, toxins are elaborated having a direct depressor action on the cells of the stomach so that they fail to react to secretory nerve impulses and secretogogues.

34. **Paroxysmal Tachycardia of Ventricular Origin.**—In eighteen cases of paroxysmal tachycardia reported by Vaughan only two, which are here reported in detail, showed a site of impulse formation elsewhere than in the auricles. Study of the literature points to the infrequency of cases of paroxysmal tachycardia of ventricular origin. To those already reported two are added. Digitalis may be an exciting cause in the production of the condition, but there must be some other predisposing factor such as ventricular hyperirritability from impaired blood supply or from some other cause.

35. **Vegetative Nervous System in Typhoid.**—In typhoid there sometimes exists striking bradycardia, even in the fever period, for which there is no satisfactory explanation. The work done by Matsuo and Murakami is an attempt at a solution of this problem through the hypothesis of Eppinger and Hess. They used typhoid patients, including seven cases of paratyphoid B, bacteriologically and serologically proved. Up to the time of examination no complication had set in. All were more than 14 years old. Patients who were in excited states were avoided. For the pharmacodynamic examination the authors used atropin, pilocarpin and epinephrin. In typhoid cases, atropin acts strongly on those patients who have marked bradycardia, but has almost no effect on those who have no bradycardia. Increase of pulse rate is the most significant atropin action; then comes increase

of thirst, and lastly palpitation. In only one case the remarkable paradoxical phenomenon, decrease of 17 in pulse rate, accompanied by arrhythmia, was observed. After injection of epinephrin, increase of pulse rate, elevation of blood pressure, acceleration of respiration and elevation of body temperature were observed in many cases. Tremor and glycosuria were often observed, but palpitation, nausea, and headache seldom. So-called dissociation of epinephrin action was observed even in cases of typhoid.

In the majority of cases salivation and sweating were observed after pilocarpin injection, besides nausea, vomiting and singultus. In only one case did the authors find a decrease of 14 in the pulse rate, accompanied by arrhythmia. This fact has never been noticed by anybody up to this time. Dissociation may be seen after pilocarpin in typhoid, but not so marked as after epinephrin. Examining the function of the vegetative nervous system in 38 cases of typhoid, the authors found 14 cases which corresponded to vagotonia, 11 cases which corresponded to sympathicotonia, 3 cases which were sensitive to all three drugs, 7 cases which were sensitive to pilocarpin and epinephrin, and 3 cases which were sensitive only to pilocarpin. In the cases with marked bradycardia, the state of vagotonia was often observed, while in those with no bradycardia, sympathicotonia was often observed. The state of vagotonia may be one explanation for bradycardia in typhoid. The deaths among these patients were all in the condition of sympathicotonia.

37. **Loss of Water Vapor Through Skin.**—It appears from a study of the experiments reported on by McClure and Sauer that the rate of ventilation has a decided effect on the amount of water vapor given off by the skin. This amount increases with the rate of ventilation up to a certain point, when it seems that a cooling effect prevents a further increase. Cotton garments, such as used in the authors' experiments, do not seem to offer any obstacle to the loss of water vapor from the skin; at least not when they have been in contact with the skin a number of hours. Such factors as fretfulness, crying and increase in the room temperature increase the insensible perspiration of the infant. The loss of water vapor from the skin of certain atrophic infants is relatively great. The loss of water vapor from the skin seems sufficiently great to make it an important factor in the heat elimination of the infant. Furthermore, this mechanism of heat elimination seems to possess a great degree of elasticity.

48 *Bird Malaria and Pathogenesis of Relapse in Human Malaria. E. R. Whitmore.—p. 62.
49 Physician's Aphorisms; Mediaeval Hebrew Satire. H. Friedenwald.—p. 67.

47. **Ureterovenous Anastomosis.**—The technic by which ureterovenous anastomosis may be accomplished successfully and leave a ureter which remains patent, is described by Read. He found that after anastomosis of the ureter into the vena cava the blood does not flow back into the pelvis of the kidney. By anastomosing a ureter into the portal or splenic vein the effect of the urine on these organs could be studied. Ureterovenous anastomosis leads to hydronephrosis unaccompanied by marked histologic changes in the kidney. The dilatation of the ureter in these cases begins at the point of anastomosis and ascends to the pelvis of the kidney. After a single anastomosis, the life of the dog, at the end of two months, remains unaffected. The urea and nonprotein nitrogen of the blood rises slightly at first but shows no tendency to increase subsequently. When both ureters have been anastomosed into the systemic venous current, the blood urea and nonprotein nitrogen continue to rise until death, about as rapidly as they do in cases of double nephrectomy. The hydronephrotic kidney secretes urine which is characterized by a low salt and a high nitrogen concentration. After double ureterovenous anastomosis the average life of the dogs in this series was six and three-fourths days. The kidneys apparently do not reduce materially the toxicity of the substances which they remove from the blood stream.

48. **Pathogenesis of Relapse in Human Malaria.**—Whitmore believes that in malaria the body produces antibodies which resist the multiplication of the parasites. But certain of the parasites become resistant to these antibodies (or to quinin) and continue the asexual cycle, the number of parasites, however, being too small to produce symptoms. When anything happens to lower the resistance of the body, these parasites are able to multiply rapidly and produce symptoms; that is, a relapse. The continuation of gametocytes is due to the continuation of the asexual cycle. As long as the infection continues, the body is stimulated to produce antibodies, and the infected person is resistant to superinfection; that is, there is a labile infection. There is no immunity after recovery; as soon as the infection is stopped by the antibody production, or by treatment, the stimulus to antibody production is withdrawn, and the person is susceptible to reinfection, just as though he had never been infected before.

55. **Cardiovascular Examinations at Camp Dodge.**—Between 25,000 and 30,000 men were sent to Camp Dodge during September, October and November, and of these 443 were referred to the cardiovascular board for defects. In the various regiments the percentages of referred examinations ranged from 0.3 to 0.6 per cent. Of these 443 cases, 163 cases were rejected (37 per cent.). The pulse rate was taken in the dorsal and standing positions, after exercise and two minutes later. It was found that the greatest change and increase in the pulse rate was in the normal heart and in the heart bordering on decompensation. In the organically diseased hearts with marked hypertrophy and excellent compensation, the change of rate was very slight from the dorsal to the standing position, after exercising and two minutes later. The greatest differences in pulse rates were seen in the so-called nervous or irritable heart. One explanation for this phenomenon is that the reserve force of the large well compensated heart is great, provided that the musculature is not diseased and has a greater waiting force than the average normal heart. A number of cases of splendid com-

pensation were seen with lack of any discomfort on exercising. A great number of men were referred because of precordial thrills. These were found to be produced by excitable hearts, no other sign of cardiac disease being detected. It was noted that thrills were most readily appreciated by gentle pressure of the examining hand.

The majority of the irregularities were of the juvenile type, increase of rate with inspiration and slowing with expiration. This was most exaggerated in those men showing symptoms of the effort syndrome of Lewis. Extrasystoles were observed in twelve cases; of these, three were without other signs of cardiac disease, in the remaining nine physical signs of definite cardiac pathology were found. Systolic and diastolic observations were made in all cases. Observations were made usually at the end of the examination. Two cases of chronic interstitial nephritis with hypertonus were seen. Several cases of hypertonus occurred associated with cardiac hypertrophy, with shortness of breath and palpitation on exertion. Cardiac hypertrophy with no cause determinate appeared six times. Asthma was associated with cardiac hypertrophy in two cases; with hypertonus in one case. Of six cases of cardiac hypertrophy (cause not determinate) some were associated with symptoms of effort syndrome while others suffered no discomfort on exertion. One man had with his hypertrophy, marked tacchycardia with dyspnea and precordial discomfort on exercise. The most interesting sounds have been the systolic murmurs heard best at the base or at the apex not associated with other physical signs or symptoms. Three cases were seen with very loud systolic murmurs heard best over the second left interspace, very widely transmitted. These were regarded as cases of possible congenital heart disease. The cardiorespiratory murmurs have been legion, systolic murmurs in second left and right interspace heard during expiration, disappearing with deep breath. Then there is the faint systolic whiff at the apex appearing after exertion. Feil says that his limited experience with the exercise test emphasizes the need of coordinating all findings before judgment is passed on the individual heart case. The slow rate of the badly damaged but well compensated heart appeared many times. The finding of a precordial thrill not associated with other abnormalities should not be regarded as cause for rejection. Extrasystoles should not be passed over lightly in the absence of other findings.

65. **Globoid Bodies of Poliomyelitis.**—Globoid bodies identical in morphologic and cultural characteristics with the organisms described by Flexner and Noguchi, have been obtained by Smillie in twenty-two cultures from the tissues of seven monkeys suffering from experimental poliomyelitis. Twenty of the strains were cultivated from the central nervous organs, all being obtained from the cerebrum except one, which was cultivated from the cervical portion of the spinal cord. Two strains were cultivated from the spleen. None of the cultivated strains inoculated produced typical poliomyelitis in monkeys. The recovery of a strain of the globoid bodies from the inoculated monkey is as difficult as is the original cultivation of the organisms from animals inoculated with the ordinary virus of poliomyelitis. Nothing in this study has served to implicate the streptococcus in the pathology of the poliomyelitic process; the streptococcus, is, however, encountered as a common contaminant or secondary invader, especially in animals which have been etherized while moribund, or which had died some hours previous to the necropsy. When the infected and paralyzed animals are killed while still strong, secondary invading bacteria, including the streptococcus, tend to be absent from the tissues.

66. **Circulating Antibodies and Serum Disease.**—Of 25 cases which were studied by Longcope and Rackemann 21 developed serum disease manifested by characteristic symptoms following intradermal injections of diluted horse serum. Of 14 cases in which the serum was tested for precipitins, 12 developed serum disease. Of the 15 patients whose blood was tested for anaphylactin, 12 developed serum disease. In 3 cases the injections of serum were not followed by serum disease. Anaphylactin could never be demonstrated in the serum drawn repeatedly from these patients. In 15 cases repeated skin reactions were made and in all of these a positive response was sooner or later observed. From these results it is evident that in the cases studied, precipitins and anaphylactic antibodies were much more likely to be found in the blood serum of patients who suffered from serum disease following the injections of horse serum than in patients who escaped serum disease. In the latter instances precipitins and anaphylactic antibodies were not observed. The skin reaction, however, made its appearance irrespective of the amount of serum administered or the method of administration and appeared whether or not serum disease developed.

67. **Immunity in Intestinal Obstruction.**—Experimental evidence secured by Dragstedt and Moorhead shows that there is no increased immunity or tolerance to intestinal obstruction after recovery from previous obstruction. Dogs recovered from intestinal obstruction are not more resistant to injections of closed loop fluid than normal dogs. Dogs injected with closed loop fluid are not more resistant to intestinal obstruction than normal dogs. In dogs the normal variation in resistance both to intestinal obstruction and to the injection of closed loop fluid is large.

68. **Antiseptics and Bacillus Welchii Toxin.**—As wounds infected with *B. welchii* are frequently encountered in military surgery today, and as the antiseptics studied are used extensively on wounds of this character, Taylor and Austin used the toxin of Bull and Pritchett and the pigeon as a very sensitive indicator of the relative toxicity of the various toxin antiseptic mixtures in a series of ten experiments. Comparable results were obtained in all. It was found that Dakin's hypochlorite and chloramin-T solutions will protect pigeons against multiple fatal doses of the toxin of *B. welchii* when the antiseptic and the toxin are mixed in vitro and allowed to stand in contact for five minutes before injection. The detoxicating action of the solutions is demonstrable also in the presence of serum. Phenol solution, 0.25 per cent., has no such action.

69. **Nucleated Red Blood Corpuscles in Peripheral Blood.**—The authors found that hemorrhage with immediate saline infusion causes the appearance in the peripheral blood of a slightly increased number of normoblasts, provided normoblasts are already present in the blood stream. Marrow hyperplasia does not intensify this reaction and the cells

found probably do not leave the marrow pulp but are in the blood stream at the time of the experiment. The slight increase in cells occurring immediately after hemorrhage and infusion is designated a pseudocrisis. True crises are much more extensive; they tend to occur just before rapid increase in the erythrocyte count and usually toward the end of the first week following hemorrhage. Red cells and white cells tend to move from the marrow together, but this association is not invariable. After repeated hemorrhages regeneration occurs independently of the appearance of nucleated red cells in the peripheral blood. Repeated hemorrhages associated with extension of erythrocyte producing marrow lead to polycythemia but not to a conspicuous increase in speed of regeneration.

70. **Reduced Oxidation.**—The results obtained by the authors are summarized as follows: Exposure of rabbits to an atmosphere of low oxygen content results in a stimulation of the cardiorespiratory systems, in an extension (hyperplasia) of red bone marrow and probably of a thyroid hyperplasia, with the further production of hydropic and hyaline degeneration in the cells of the parenchymatous organs. An atmosphere of high carbon dioxid and normal oxygen content produces, however, a stimulation of the cardiorespiratory systems, but no marrow extension and, in the concentrations used, but slight hydropic degeneration in the parenchyma of the glandular organs.

72. **Pure Vaccine Virus Cultivated in Vivo.**—Noguchi studied the effect of disinfectants on the testicular vaccine virus at different temperatures, the influence of diluents under various experimental conditions, the effects of desiccation on the virus, and the viability of dried vaccine. The virulence of vaccine virus for the testicular tissues increases until its maximum is finally reached. The testicular strain of vaccine virus has no more tendency to localize in various organs than the ordinary skin strain. Intravenous inoculation of an excessive amount of a powerful vaccine virus (1 to 2 c.c. of undiluted stock emulsion), irrespective of whether it is from the testis or the skin, will result in a generalized eruption over the entire body surface of rabbits. Subcutaneous or intravenous introduction of much smaller quantities of the virus does not cause an appreciable local or general reaction in the rabbit. Experiments on the viability and resistance of the testicular strain of vaccine virus indicate that the virus is best preserved when emulsified with Ringer's solution or 0.9 per cent. saline solution. Of the two most commonly employed chemical agents for the ripening (eliminating bacteria) process of the green vaccine pulp, glycerol and phenol, the latter is the less injurious. Phenol in concentration above 2 per cent. destroys the virus within twenty-four hours at any temperature, but it has almost no injurious effect when used in 0.5 to 1 per cent. On the other hand, glycerol is a powerful vaccinicide. When used in full strength it destroys the virus within twenty-four hours, even at 4 C. The vaccine virus retains its virulence better in a sealed tube containing either hydrogen, nitrogen, or air than in an open receptable. The virus deteriorates when placed in a sealed tube with oxygen or carbon dioxid. Desiccation decreases to a considerable degree the virulence of the vaccine virus. Iodin is a powerful disinfectant for the vaccine virus, but its sodium and potassium salts have no effect.

73. **Survival of Poliomyelitic Virus in Brain.**—The experiments recorded by Amoss provide additional reasons for concluding that the streptococcus cultivated from cases of poliomyelitis differs essentially from the filterable virus and is not the microbic cause of epidemic poliomyelitis.

4 Thigh Stump Extension Splint. W. E. Fisher.—p. 229.

1. **Penetrating Wounds of Brain.**—The net results of Cushing's study of head cases admitted to three contiguous hospitals during a period of three weeks were as follows: Taking as 100 the total number of cases admitted with an initial diagnosis of some form of "head wound," the percentage with dural penetration was 23.5. Taking the verified cases alone the percentage with dural penetration was 49.3. Of these 49.3 per cent. verified cases approximately one third died without operation, their injuries being either of extreme gravity or multiple. Of the remaining two thirds, all were submitted to operation, and exactly half of the patients subsequently died, thus giving the generally accepted 50 per cent. operation mortality for wounds of this type. For comparison the following figures covering the whole three months may be given for the cases that came under the supervision of Dr. Cushing's team. Of the cases submitted to operation, 10.9 per cent. proved to have merely scalp wounds, 23.7 per cent. cranial wounds with intact dura, 60.7 per cent. cranial wounds with dural penetration and 4.5 per cent. bursting fractures of the cranium but with the scalp and dura both intact. During the initial two weeks the operation mortality for the author's own team was above the average figure for all the hospitals together. This may be accounted for in some measure by the fact that during this period, as also during the entire three months, wounds of the more serious type were deliberately selected from among the cases retained at the hospital. This is indicated by the relative height of the percentage of cases with dural penetration (60.7) as compared with the corresponding percentage (49.3) for the whole of the verified cases during the first two weeks.

Of 225 cases, 6 patients died without intervention, the remaining 219 were operated on, and 133 proved to have dural penetration. The net results are best shown by dividing these 133 cases into thirds roughly corresponding with each consecutive month of service. First, 44 cases with 24 deaths = 54.5 per cent.; second, 44 cases with 18 deaths = 40.9 per cent.; third, 45 cases with 13 deaths = 28.8 per cent. These percentages are practically end results, for no cases were evacuated until they had passed the stage of conceivable complications, and Cushing believes they are sufficiently encouraging to justify the hope that a still further lowering of the mortality may be attained, and that in an advanced hospital 75 per cent. of recoveries is not too large a figure to be set as a goal. During the three month period an operation, with certain technical devices applicable to the average penetrating wound, was gradually evolved. Aside, possibly, from the principle of track suction there is nothing original about the procedure, nor are the instruments new.

The main features of the procedure lie: 1. In the removal en bloc rather than piecemeal of the area of cranial penetration. 2. In the detection of the indriven bony fragments by catheter palpation of the track rather than by the exploring finger. 3. In the suction method of removal of the disorganized brain, thereby cleansing the track of the so-called pulped or devitalized tissue, whose retention, as is the case with dead tissue anywhere, favors infection. 4. In the use of dichloramin-T in oils as an antiseptic particularly suitable for infections in the central nervous tissues. In addition to these more essential features of the performance, the routine preoperative neurologic study of the case stereoscopic roentgen-ray negatives, the shaving of the entire scalp, the invariable use of local anesthesia, preferential radial (tripod) rather than flap incisions, foreign body extraction with the magnet when possible, closure of the wounds with buried sutures in the galea, the dressing of all serious cases in the operating room rather than in the wards, all these steps, though less novel, Cushing says, were, nevertheless, contributory to the successful outcome of the more severe cases.

2. **Extraction of Foreign Body from Brain.**—The extractor used by Rayner and Barclay is made like a pair of dental forceps, the jaws being about 1 ½ inches apart when closed. Above the jaws is fitted a small fluorescent screen. Beaks or blades are fixed at right angles to the jaws and meet at the points, but are insulated from one another by a small fiber block let into one of the blades, which is made slightly longer than the other. For brain work the blades are thin and close together, the point of the longer blade being rounded. For the removal of foreign bodies from ordinary tissues stronger blades are used, the point being fashioned like a blunt dissector so that the instrument can dissect, and, by opening the blades, separate its own way down after the skin incision has been made. The blades are connected with an electric bell through a relay that is specially fitted in order to avoid stimulation of structures when contact is made. When the blades are brought into the correct relationship with the foreign body, that is, with the longer blade alongside and the shorter blade touching the top of the fragment—contact is made and the bell rings. This indicates that by raising very slightly and opening the blades the foreign body can be picked up without any intervening structures being also caught. Protection, additional to that of the diaphragm, tube, box, etc., is afforded by a sheet of heavy roentgen-ray proof rubber with a 3-inch hole in it that is placed either above or below the patient.

7 *Case of Metastatic Cancer of Bone Marrow without Erythroblastic Reaction. W. R. Jack and J. H. Teacher.—p. 81.

7. **Metastatic Cancer of Bone Marrow Without Erythroblastic Reaction.**—A man, aged 58 years, was admitted to the hospital with a history of pain in the stomach, nausea, vomiting and occasional attacks of diarrhea of two years' duration. His family history was negative. He had had no other illnesses but those of childhood, and he had suffered

two years previously from a fracture of the right femur, which had healed normally. About that time, or shortly afterward, he began to complain of abdominal pain coming on soon after food, and followed by vomiting, the food coming up in mouthfuls without much feeling of sickness, and having a very bitter taste. He never vomited either blood or "coffee-ground" material. These symptoms were accompanied by loss of flesh and strength, and by occasional sharp attacks of diarrhea, the stools, however, never being noticeably dark. As his condition rapidly deteriorated, he was operated on a year ago. A large malignant tumor was found in the stomach. As it was inoperable, a gastro-enterostomy was performed, and from this he got some relief for a time, although his pain after meals never entirely disappeared, and ultimately became severe enough to keep him from eating in spite of a craving for food. It was always relieved by vomiting, and was localized to the upper epigastrium. Emaciation also rapidly progressed.

At the time of the second admission no definite tumor could be palpated, but there was distinct rigidity of both recti, and in the middle line just below the xiphoid cartilage there was a localized area highly tender to palpation. No dilatation of the stomach could be made out. Neither liver nor spleen was enlarged; no enlarged glands were to be found in the neck; and the urine was normal. Gastric analysis after a testmeal revealed an almost complete achylia, the total acidity being 2, with no free hydrochloric acid, and only a trace of lactic acid. His condition went from bad to worse, and about ten days after admission he began to complain of pain over the lower end of the sternum, where pressure on the bone elicited tenderness. A little later he had also pain in the back, in the region of the lumbar vertebrae. As bony metastases were suspected, the blood was examined. The red cells numbered 3,390,000 per c.m., the white cells 15,000; hemoglobin 45; color index 0.67; moderate poikilocytosis; no nucleated red cells nor polychromatophilia. The blood picture was that of an anemia of the chlorotic type, with no evidence of erythroblastic reaction. The bone pains increased in severity, and were also felt over the lower ribs on the left side. He gradually sank, and died four weeks after admission.

Postmortem examination: The pyloric region was occupied by a tumor about the size of a tennis ball, which completely encircled the organ. Several glands were invaded by tumor close to the primary growth. No obstruction of the bile ducts. Bones: There were a number of small secondary tumors in the lower part of the sternum, and another in the lower part of the manubrium sterni. There was a large mass occupying about 3 inches of the eighth rib which had extended into the pleural membrane over a considerable area. The fourth right and seventh left ribs were easily broken owing to the presence of tumor; the other ribs were quite strong. There was an old fracture about the junction of the upper and middle thirds of the right femur. This was not due to tumor. The marrow in the middle of the left femur was fatty, with one small red area which appeared to be a tumor. There was, therefore, no marked erythroblastic reaction. There were a few small nodules in the tenth and eleventh vertebral bodies, and there was a marked osteo-arthritic thickening between the eleventh and twelfth vertebral bodies.

41 *Palpation of the Cecum. L. Pron.—p. 119.
42 *Intermittent Reunion for Infected Amputation Stumps. H. Chaput.—p. 121.

39. Summarized in Paris Letter, p. 796.

41. **Palpation of the Cecum.**—Pron gives his conclusions from palpation of the cecum in 123 subjects. It was palpable in about 50 per cent., and there was pain on pressure in some others, so the cecum was found abnormal in 63 per cent. It varied in shape, place and consistency at different hours in the same subject, but a direct connection was apparent between the pain that could be induced in the cecum and abnormal conditions in the liver. In 50 patients with some form of liver trouble, the cecum was palpable or painful in 32. Still more significant is the finding of abnormal conditions in the cecum in 72 out of 108 cases of stomach disease with objective findings. Hence the discovery of a palpable cecum or pain on pressure should attract attention to the liver or stomach. As sounds of fluid contents can be heard in the cecum even during prolonged constipation, there is a possibility that the cecum is an organ with a secretion of its own.

42. **Intermittent Reunion of Infected Amputation Stumps.**—Chaput expatiates on the advantages of exposing the infected stump to the air during the day, turning the flaps of soft parts back and fastening them to expose the stump to the air as it rests on a pad. At night he restores the flaps to place, over capillary drains or sheets of rubber tissue, holding the flaps in place with plaster strips. Traction is applied to them as soon as the infection is conquered. Healing has been complete in two or three weeks as a rule with this technic as applied in several cases.

44. **Record of the Pulse.**—Barré has combined the Marey plethysmograph with the Vaquez sphygmotensiometer and uses two pneumatic cuffs, one just below and one just above the elbow. The elbow and wrist rest on cushions so that neither cuff touches the table. He gives illustrations and tracings and tells how to interpret the record to determine by the tracing the exact maximal and minimal pressure.

45. **Epididymitis after Meningitis.**—The meningitis had been caused by a parameningococcus resembling the gonococcus in its fermenting capacity.

46 and 47. **Parameningococci.**—Bloch and Hébert relate that in the cases of epidemic meningitis on the eastern firing line parameningococci are often found. They agglutinate specifically and yield only to a bivalent antiserum. Netter's experience also emphasizes the efficacy of polyvalent antiserums.

48. **Infectious Antecedents in War Tachycardias.**—Crouzon and Mauger state that in ninety-six cases of tachycardia in soldiers on active service they found over 50 per cent. with a history of typhoid, acute articular rheumatism or other infectious disease, nearly all before the war. In four other cases the tachycardia developed after gassing; in four after concussion, and in two after a wound of the chest. Dumas, in the discussion that followed, remarked that he had sometimes found tachycardia an early symptom of pulmonary tuberculosis. He added that some of the candidates for the aviation course came from the front with tachycardia, but it subsided under rest and restriction of tobacco and alcohol. The men were anxious to get to flying and they usually threw off the tachycardia. The power of psychic influence is well shown, Josué added, by the tachycardia that develops in men being examined for the aviation course; it develops solely, he declares, from the candidates' fear of being rejected.

49. **Uremia from Cardiovascular Causes.**—Josué and Parturier describe two clinical cases which confirm their previous statements that oliguria for which the heart is responsible may entail uremia of 1 gm. or thereabouts and realize the clinical picture of uremic intoxication. By measures to induce polyuria all the uremic symptoms disappear. There may even be a relative oliguria with apparently ample diuresis, that is, although the output of urine may be considerable, yet it is less than the amount required for complete excretion of the urea. In both forms polyuria must be induced as the primal indication. With a damaged kidney, the prognosis depends on the ability of the heart to maintain the compensating polyuria, so that, as they say, the future of the *brightique est dans la résistance de son myocarde.* When the urea was in the blood in proportions above 1 gm., they never were able to increase the diuresis, and the uremia continued a progressive course. With uremia from oliguria in a patient with asystoly, digitalis must be given freely to bring on the liberating polyuria. The urea content of the blood then drops to normal. In one of the cases described there was albuminuria, Cheyne-Stokes breathing, high blood pressure and aortic stenosis, but all the symptoms melted away when the polyuria set in. Theobromin was then given with the digitalis to keep up the diuresis.

56 *Habitual Constipation in Infants. H. Dorlencourt.—p. 20.
57 Gelatin Tannate in Diarrhea. E. Choay.—p. 41.
58 Commercial Modifications of Cow's Milk. A. B. Marfan.—p. 43.

55. **Meningitis in Infants.**—Hallez has been making a special study of the reasons why serotherapy of meningitis so often fails, especially in infants. The main cause is that the meningitis develops as in an enclosed cavity. Marfan calls this type of cases *méningite cérébro-spinale cloisonnée, avec épendymite, évoluant en cavité close.* Chiray has described such cases in adults, grouping them as *pyocéphalic.* In another group of cases the meningitis may be accompanied with hydrocephalus, or there may be ependymitis with posterior basilar meningitis, or encysted meningitis at different points. Hallez reviews the literature on these four main types of meningitis, and describes the clinical picture with each in infants. He has encountered twenty-four cases of the partitioned-off type, nine in young adults, two in girls of 11 and 13, and thirteen in infants from 2 to 24 months old. The return of symptoms after they had subsided under serotherapy, the taut and protruding fontanel, which does not relax after lumbar puncture, the emaciation, and the alternation of redness and pallor in the skin, eruptions and profuse sweats or abnormal dryness of the skin suggest that the meningitis is developing in some enclosed cavity. The infant's torpor is interrupted by moans and cries, except when feeding—all signs of the localization in the ventricles and excessive pressure. Hearing or vision may be materially impaired. The motor disturbances may include a tetaniform stiffness and a variable degree of paresis, with or without tremor in respose. Convulsions are rare, but monoplegia of a plastic type has been encountered. If the ventricles contain pus, the temperature may run up again.

Lumbar puncture is instructive by the negative findings in the fluid, the approximately normal fluid contrasting with the aggravation of the clinical symptoms, or there may be very little fluid in the spinal canal, or it may show that the antiserum injected two or three days before was not absorbed. The decisive sign is the difference between the comparatively clear spinal fluid and the purulent fluid that can be aspirated from the ventricles. He has never found percussion of the skull instructive. Injection of fluid into the spinal canal in an amount equal to or surpassing the amount withdrawn is liable to bring on convulsions as the usual safety valve is lacking. The spinal meningitis may have been so insidious and so slight that it escaped detection; this type is particularly liable to involve the ventricles as the serotherapy is not applied early, and hence the disease gets a good start.

Treatment is by direct injection through the fontanel into the ventricles of a polyvalent antiserum while the same is injected into the spinal cavity to ward off further localization of the meningitis. When bacteriologic examination has revealed the special germs involved, then the specific antiserum can be used. After the lumbar injection, he raises the pelvis so that the fluid can lave the higher centers. Ramond advises also turning the child on its stomach for twenty or thirty minutes so that all parts of the cerebellum, etc., can be laved. The same doses of the antiserum can be given for three or four days. Injection directly into the ventricle is simple and easy in infants. The needle is introduced in the outer corner of the fontanel, about 2.5 cm. from the median line. Hallez has done this himself and seen it done numbers of times for meningitis or hydrocephalus and has never witnessed the slightest mishap from it. The needle is pointed at the auditory canal of the ear on the other side, slanting it at an angle of about 20 degrees; it is pushed in from 2 to 4 cm., thus usually piercing the second frontal convolution. When the cavity of the ventricle is reached, fluid escapes from the needle. He generally aspirated 30 or 60 c.c. and then injected 20 or 30 c.c. of the antiserum without modifying the direction of the needle. These injections can be repeated for several days. It seems best to inject the antiserum into both ventricles.

This method of treatment has been applied generally only as the last resort, and consequently few were saved, none in Netter's eleven cases and only four of Hallez' eleven, but with earlier recognition of the partitioning-off of the meningitis, better results may be anticipated. Lesage advocates an injection into each ventricle, from the first along with the intraspinal injection, as a routine measure and reports excellent results in two cases. It is possible that vaccine therapy might prove effectual when there are multiple foci. In a case reported by Suner no fluid escaped from the ventricle when the needle was introduced, but still he injected the antiserum. Necropsy showed that the meningitis had been restricted exclusively to the base of the brain.

56. **Habitual Constipation in Infants.**—Dorlencourt restricts his discussion to infants fed exclusively on milk, breast or bottle. He regards an infant with one stool a day as already subject to a certain degree of constipation. Two or three days without a passage is confirmed constipation. He insists that a purgative or laxative should never be given except as the last resort. Enemas may be useful in certain cases. They should always, he says, be given hot, and composed of physiologic serum, an emulsion of oil, or pure oil. They are contraindicated with atony of the bowel as they would only increase it, while frequently repeated lavages would deprive the mucosa of its last traces of sensibility. In this case they should be used cold and of small volume. Whatever the type of constipation, enemas should never be allowed to become a regular practice.

He emphasizes the necessity for differentiating the cause in order to apply proper treatment. In the constipation connected with atony, all measures to stimulate the organism should be applied, including general salt baths followed by rubbing with alcohol (or a very little turpentine) and massage of the abdomen. When the atony seems to be due to weakness of the reflexes, and this is traceable to anesthesia of the mucosa, immediate and often remarkable results can be obtained by introducing into the rectum a blunt tipped cannula or glass stirring rod. This is left in contact with the mucosa for a few minutes, moving it around a very little. The mere presence of this foreign body, its light rubbing of the mucosa, usually entail an evacuating reflex. This simple procedure can be tried in all forms of constipation, and has numerous advantages over other measures for the purpose. When the constipation accompanies a large flabby abdomen, the child should wear constantly a broad flannel abdominal band, extending up on the chest. In the forms of constipation with signs of hypertonicity, instead of salt baths the child should be given tepid baths and have hot compresses applied to the abdomen for several hours during the day. With both atony and hypertonus, the children should be kept out of doors. He adds, *les promenades au grand air stimulent les atoniques, calment les nerveux.*

The passage of hard feces causes erosion of the mucosa of the anus, and the pain from this causes the child to repress desires to defecate, or may induce spasm of the sphincter. Silver nitrate will help cure the fissure and treatment of the constipation will break up the vicious circle. He reiterates that laxatives do not cure constipation and they are liable to bring on a diarrhea worse than the constipation or they may be followed by aggravation of the constipation. Marfan's choice is sodium citrate; it can be given up to 1.5 to 2 gm. a day without harm. Calomel should never be used for constipation in infants. He has known it to bring on severe acute dysenteriform enterocolitis. When the constipation is the result of hypertonus or spasm, belladonna may be indicated. Dorlencourt gives it in pulverized form, 0.004 gm. per year of age, with some mild laxative such as podophyllin. He warns against combining it with magnesium salts as their action is exactly opposite.

66 Jaundice After Galyl Treatment of Syphilis. Veillet.—p. 109.

59. **Administration of Epinephrin.**—Milian has been preaching since 1913 that epinephrin properly administered will ward off and cure all disagreeable or alarming by-effects of treatment with salvarsan and its substitutes. A number of clinicians have confirmed the efficacy of epinephrin in this line, but still it does not seem to be as generally known as it should be. The French dispensatory specifies only homeopathic doses, not over 1 mg. in the twenty-four hours. Martinet advocates up to 2 mg. in twenty-four hours, testing the tolerance, but Milian asserts that he has given 2, 3 and even 4 mg. of epinephrin within a few minutes, to ward off the threatening immediate or tardy dangerous congestion from the salvarsan. The intravenous route should be reserved for serious emergencies, and a small dose, amply diluted, should be the rule, for example, 100 c.c. of artificial serum containing 0.1 mg. of epinephrin. This solution arrested at once an asthmatiform nitritoid attack, with no objective by-effects beyond slight pallor of the face and rapid rise in the blood pressure. There was no tachycardia until after a second injection of half the dose.

Milian's extensive experience has confirmed the advantages of giving epinephrin before the salvarsan. To ward off the reaction to the intravenous injection of the salvarsan (fever, headache, vomiting, diarrhea, etc.) he gives 2 mg. of epinephrin in a little water by the mouth one hour before and repeats it five minutes before the injection and again an hour after it. It is also advisable to give 1 mg. by the mouth morning and evening on the four following days, when the patient is inclined to be intolerant to salvarsan. To ward off the immediate nitritoid crises (congestion of the face, vomiting, distress, etc.) he gives in the place of the dose by the mouth, five minutes before the injection, a subcutaneous injection of 1 mg. of epinephrin and an intramuscular injection of 0.5 mg. The signs that the patient is duly under the influence of the epinephrin are the blanching of the face—the leukoreaction, he calls it—the rise in the arterial pressure, tachycardia and generalized tremor. The pallor of the face is the most instructive of these signs. When salvarsan serous apoplexy has developed, the doses must be large enough to be promptly effectual. In a typical case described, a frail man of 32 with syphilitic perforation of the palate had been given 0.45 gm. novarsenobenzol by the vein. During the third night thereafter, agonizing headache developed suddenly, and the intern gave 0.25 mg. epinephrin by the mouth. By morning the man was unconscious, the eyes open, temperature 39.5 C. (103 F.), and 2.5 mg. epinephrin were given by the mouth. This induced some improvement but he still lay motionless an hour later, the eyes open but no movement of the eyeballs and no winking. Then 1 mg. epinephrin was injected intramuscularly and 0.5 mg. under the skin, and in a minute the man seemed to come to life again, looking around, drawing up the bedclothes, etc. Milian suggests that extracts of other glands with an internal secretion might advantageously supplement epinephrin. It is possible that the glands along the sympathetic system have a special action on the circulation in their special region. Epinephrin displays something of this specialized action, as it does not seem to have much influence on the cerebral vessels and the coronaries while it acts strongly on the neighboring aorta. The pituitary body may perhaps have more control over the cerebral and coronary arteries.

60. **Diagnosis of Syphilitic Primary Sore.**—In Bodin's experience, the primary lesion was multiple in about 20 per cent. of his cases; there were eleven chancres in 2, and one case each had seven and ten. In some of these cases preceding scabies in the region offered numerous portals of entry for the spirochetes, and the primary lesions developed simultaneously; in other cases they developed in series. In some cases the chancre spread over an extensive area, the aspect that of a large infected wound, sometimes gangrenous. In 4 of his 627 cases the primary lesion was only 2 or 4 mm. in diameter, but the glands were enlarged even beyond the

average. In 2 cases the base of the chancre was soft but the swarms of spirochetes confirmed the diagnosis. The glands were enlarged in all but 3 of his 627 cases; in 5 the adenitis suppurated. In 12 the chancre was in the meatus or urethra; in 67 cases phimosis masked the chancre; in 8 cases soft chancre complicated the primary lesion. He warns further that herpes lesions may become indurated after application of caustic drugs; only the history of the case will clear up the diagnosis.

61. **Influence of Trauma in Localization of Syphilitic Lesions.**—Lacapère and Laurent relate that in their forty cases of gummatous syphilitic lesions treated at the dispensary at Fez, Morocco, in fourteen cases the gummas were on the forehead. This can be explained only by the predisposing influence of the trauma when the men kneel in prayer according to the Mohammedan custom, with the brow resting on the stone floor of the mosque. Five times a day the faithful thus prostrate themselves from ten to twenty minutes, and their brows show the effects of this frequent prolonged contact with the stone floor.

62. **Febrile Reaction in Treatment of Syphilis.**—Goubeau explains that fever developing within a few hours after the injection of arsenobenzol is connected with the syphilitic infection itself, and is a sign of its activity and intensity. It is equivalent to a positive Wassermann reaction. It is not a sign of intolerance for the drug, and it does not contraindicate the continuance of the specific treatment. But when the fever develops or is continuous during the interval between injections, this intercalar fever is a sign of intolerance or of intercurrent disease, and calls for the moderation, suspension or complete arrest of the specific treatment.

75 *Social Insurance. O. Naegeli.—p. 97.
76 *Deafness in Schoolchildren. E. Schlittler.—p. 108.

75. **The Practical Medical Side of Contract Practice.**—The introduction of compulsory social insurance into Switzerland imposes new tasks on the general practitioner, and Naegeli discusses how he can best meet them and avoid being imposed on. It lies in the hands of the physicians whether the social insurance is to be a blessing or a bane for the common people. There are six great drawbacks to social insurance. Among them is the arousing of greed in the insured, and discontent, the effort to obtain unjustified advantages in the form of unduly long rest from labor and unduly high indemnity and excessive use of drugs and dressings. Besides these three disadvantages, there are the excessive demands made on the physician's time so that quiet, thorough examinations are practically impossible, and the physician feels constantly dissatisfied and is unable to make progress in his scientific attainments, while the patients suffer. The physician's dependence on the insurance company is galling, and takes all the joy out of the actual practice of his profession and may almost completely undermine his self-reliance in medical and other matters. Last but not the least of the drawbacks, is the inability to maintain the personal factor in the treatment of the sick, and hence is lost all chance for the important psychic factors.

These drawbacks can be overcome if the physician goes to his task with confidence in his skill, sympathy, and strength of character. He must not shrink from protesting against being given more clients than he can handle, and he must make a point of thorough examinations. The insured are not anxious to be cured quickly, so thorough examinations meet with less obstacle than among the noninsured. Another point on which Naegeli insists is that a record should be kept of every case, with findings in heart, lungs and abdomen, whatever the trouble for which treatment is sought. Especial notice and record at the first examination and later should be made of the man's mentality. The urine should also be examined for albumin and sugar, but this can be done by an assistant. The ultimate outcome of each case should be added to the record. These records are especially important from the oversight they permit of the man's psychic behavior during the course of the case. His wishes and longings and the motives for them should be carefully recorded. The anamnesis is particularly important in case of a neurosis. In dubious cases, consultations should be demanded without waiting too long. Arrangements can often be made for this with the medical department of the nearest university.

The main thing, Naegeli reiterates, is the diagnosis, and this includes diagnosis by exclusion of simulation and exaggeration. Detection of these requires not only great medical knowledge and medical confidence but great psychologic talent, as the decision as to the simulation must be based usually merely on the physician's impressions. This is not enough for others, and this alone is enough to justify caution in affirming simulation. In dubious cases it is a wise plan to pass judgment on the man's condition only as it modifies his earning capacity. Although you do not assert that the man is malingering, yet you can report that his earning capacity is reduced very little if at all.

Naegeli warns of the necessity for extreme caution as to simulation in all cases in which there has been concussion of the brain, atheroma, multiple contusions and psychopathic factors. With hysteria, the complaints are constantly varying; the simulator sticks to his one trouble which is "always the same." With hysteria, the man is so convinced of his trouble that he is sure the physician will be convinced too, and he wastes no words trying to convince him, while the simulator keeps affirming the truth of his statements. The latter insists that he cannot be cured and makes no attempt to train himself to increase his earning capacity while the man with hysteria wants to be cured and rejoices at his progress. Mild hysteria and simulation are sometimes associated, and a tendency to a psychosis renders the whole problem more difficult of solution.

76. **Special Schools for the Deaf.**—Schlittler states that Basel opened last year three schools for children who are hard of hearing. All the children who could not hear a whisper at 6 feet were examined by a specialist. It was found that over three fourths of them had some curable ear trouble, and it was learned further that the hearing of about one fourth of all the supposedly normal children was somewhat impaired. Another significant discovery was that seven tenths of all the children in the classes for backward pupils had some ear disorder. In conclusion he reiterates the importance of seeking out and curing all curable cases of deafness, if for no other reason than to prevent such a loss to the military service when these children reach the military age.

Bolletino dell'Istituto Sieroterapico, Milan

November, 1917, **1**, No. 2

77 Recurrences in Experimental Infection with Spironema Recurrentis. G. Castelli.—p. 57.
78 *Agglutination Tests for Cholera. P. Negroni.—p. 75.
79 *Diagnosis of Meningitis. L. Vigano.—p. 85.
80 Vaccination of Civilian Population Against Typhoid. A. Pugliese. —p. 93.
81 Composition of the Blood in Aviators. A. Gemelli.—p. 105.
82 *Serotherapy in Infectious Jaundice. R. Inada and Others.—p. 111.
83 Distribution of Spirochetes in Organs in Infectious Jaundice. R. Kaneko and K. Okuda.—p. 131.

78. **Prophylactic Value of Agglutination in Cholera.**—Negroni's research has confirmed the value of agglutination tests for distinguishing the true cholera germs from those that resemble them. No agglutination was ever noted with the pseudocholera germs in dilution beyond 1:500 and very rarely up to this, while with true cholera germs it occurs at 1:10,000 and even at 1:100,000. The agglutination at 1:100,000 is complete in four hours with the living germs, but with germs killed with phenol it occurs in four hours only with dilutions of 1:1,000; seven hours, 1:20,000, and fourteen hours with 1:50,000.

79. **Diagnosis of Meningitis.**—Vigano remarks that agglutination occurs too late for it to have much diagnostic value, but some have reported instructive findings with the deviation of complement test, and others with the opsonic index. The precipitation test of the cerebrospinal fluid treated with an antimeningococcus serum gave a positive response only in six. These had been tested the second, third, eighth or fifteenth day. Microscopic findings were more reliable, the findings being positive in twenty-four of the thirty cases, and cultures developed in eleven. Negative findings with these tests must be compared with the clinical findings. In one case a young man with severe meningitis, fatal the seventh day, had always shown a limpid and sterile spinal fluid. Necropsy showed adhesions between the cerebellum and the medulla partitioning off the space below, and the fourth ventricle was paved with pus.

82. **Spirochetosis Icterohemorrhagiae.**—The results realized by Inada and his co-workers with intravenous injection of antiserum in forty-one cases apparently confirm the superior efficacy of this route. They declare that, in rabbits, five minutes after the intravenous injection of 0.5 of the antiserum per kg. of weight, the antibodies appeared complete in the blood. With subcutaneous injection they appear only in an incomplete form and not until after eight hours. This passive immunity lasted for three or four days. The clinical experiences were most encouraging. The cases are tabulated and compared with cases in which the subcutaneous route was followed. The intravenous serotherapy seemed to act favorable on the hemorrhagic diathesis, the pulse and purulent complications. A chill with brief fever followed the injection on three occasions. They add that 18 of the 41 patients given this intravenous serotherapy developed more or less pronounced disturbances in vision later. It was quite severe in 8. Of these 18 patients, 10 had had the disease in a severe form, 5 in a moderate form, and in 3 the courses had been atypical. Vision was reduced in 5 who had had the severe form, in one with moderate and 2 with the atypical forms.

84 *Frost-Bitten or Frozen Feet and Hands. D. A. Mazzolani.—p. 101.
85 Suggestions for Improving Surgical Service at the Front. G. Dragotti.—p. 107.

84. **Freezing Injuries.**—Mazzolani comments on the extreme importance from the military standpoint of frozen feet and hands, not only because of the suddenness of the disability from this cause, but the fact that the same cause is liable to act on numbers of men at once and incapacitate them for a long time. His experience has demonstrated beyond question that certain men are more liable to get their feet frozen than others, and at a temperature which others stand perfectly. These predisposed men should be sifted out and should not be sent to posts where freezing is likely. Frost-bitten limbs can be cured if taken in time. In the Red Cross hospital in his charge 23 per cent. of the patients in the early winter of 1915 were cases of frost-bite or freezing. Africans, the debilitated, the over-young, and the over-old, the homesick, those with heart disease, and those who have been frostbitten at some time are peculiarly predisposed to freezing injuries, as also the dyspeptic and those inclined to gouty arthritis. If men in these categories cannot be kept out of posts where freezing is liable, it might be well to give them some tonic at the time.

Jan. 26, 1918, **19**, No. 4

86 *Primary Diphtheria of Skin and Genitals. E. Mondolfo.—p. 37. Commenced in No. 3, p. 25.

86. **Primary Diphtheria of the Skin.**—Mondolfo reviews the literature on wound diphtheria and cutaneous or genital lesions in which diphtheria bacilli were found. Only four cases have been published in accessible literature in which these bacilli were found in ulcerations around the anus while none could be cultivated from the air passages. Mondolfo adds another case to this last group. The male child of 3 convalescing from mild measles showed extreme prostration for which no explanation could be found for two days, when ulceration developed on the genitals and around the anus and exceptionally virulent diphtheria bacilli were found in them in almost pure cultures. Notwithstanding vigorous antitoxin treatment the child soon died. A year later he had a similar case, a girl of 2 was brought to the hospital with diagnosis of vulvar erysipelas, but the pure cultures of diphtheria bacilli found in the lesions were evidently responsible for them. The bacilli were cultivated both from the vulvar secretions and from the nose and throat, but the nose and throat seemed of normal aspect. In both cases the cutaneous lesions had been unmistakably the primary affection. It had not been differentiated until such a late stage that recovery was scarcely to be hoped for.

87 *Congenital Syphilis. J. S. Covisa.—p. 65.
88 *Migrating Pneumonia in Children. A. R. Lozano.—p. 80.
89 *Pituitary Insufficiency. G. R. Lafora.—p. 94.

87. **Congenital Syphilis.**—Covisa describes eight cases of post conceptional syphilis in which thorough treatment cured the woman, and the child was born apparently free from any traces of the disease. The salvarsan or its substitutes must be given cautiously in such cases as the woman's heart and kidneys are already bearing the extra strain of the pregnancy. None of the twenty-three pregnant women he has treated in this way showed any symptom or signs of intolerance or by-effects of any kind. The Wassermann reaction in young infants is often unreliable.

88. **Migrating Pneumonia in Young Children.**—Instead of the pneumonia being restricted to one lobe, it spread through the entire lung in over 10 per cent. of Lozano's sixty-five cases of pneumonia in children. In these seven migrating cases the children were between 1 and 3 years old. The other lung and the bronchi never seemed to be involved, and there was no preceding rhinopharyngitis. The seven children all recovered although the course was unusually long; in some two months elapsed before recovery was complete. This long course renders nourishing feeding particularly important, especially as the children have no appetite. In one of his cases the child was fed by a catheter introduced through the nose. The children must be given water freely; this is as necessary as or even more so than food. An airy, well ventilated room is indispensable, protecting the child against drafts and getting chilled. Antipneumococcus serum and diphtheria antitoxin were given in some cases; they did not display any specific action, but seemed to be a useful stimulant. Steam in the room aids in relieving the cough; oxygen may be useful if there is much dyspnea, although it is less effectual here than in bronchopneumonia.

average. In 2 cases the base of the chancre was soft but the swarms of spirochetes confirmed the diagnosis. The glands were enlarged in all but 3 of his 627 cases; in 5 the adenitis suppurated. In 12 the chancre was in the meatus or urethra; in 67 cases phimosis masked the chancre; in 8 cases soft chancre complicated the primary lesion. 75 *Social Insurance. O. Naegeli.—p. 97.
76 *Deafness in Schoolchildren. E. Schlittler.—p. 108.

75. **The Practical Medical Side of Contract Practice.**—The introduction of compulsory social insurance into Switzerland imposes new tasks on the general practitioner, and Naegeli discusses how he can best meet them and avoid being imposed on. It lies in the hands of the physicians whether the social insurance is to be a blessing or a bane for the common people. There are six great drawbacks to social insurance. Among them is the arousing of greed in the insured, and discontent, the effort to obtain unjustified advantages in the form of unduly long rest from labor and unduly high indemnity and excessive use of drugs and dressings. Besides these three disadvantages, there are the excessive demands made on the physician's time so that quiet, thorough examinations are practically impossible, and the physician feels constantly dissatisfied and is unable to make progress in his scientific attainments, while the patients suffer. The physician's dependence on the insurance company is galling, and takes all the joy out of the actual practice of his profession and may almost completely undermine his self-reliance in medical and other matters. Last but not the least of the drawbacks, is the inability to maintain the personal factor in the treatment of the sick, and hence is lost all chance for the important psychic factors.

These drawbacks can be overcome if the physician goes to his task with confidence in his skill, sympathy, and strength of character. He must not shrink from protesting against being given more clients than he can handle, and he must make a point of thorough examinations. The insured are not anxious to be cured quickly, so thorough examinations meet with less obstacle than among the noninsured. Another point on which Naegeli insists is that a record should be kept of every case, with findings in heart, lungs and abdomen, whatever the trouble for which treatment is sought. Especial notice and record at the first examination and later should be made of the man's mentality. The urine should also be examined for albumin and sugar, but this can be done by an assistant. The ultimate outcome of each case should be added to the record. These records are especially important from the oversight they permit of the man's psychic behavior during the course of the case. His wishes and longings and the motives for them should be carefully recorded. The anamnesis is particularly important in case of a neurosis. In dubious cases, consultations should be demanded without waiting too long. Arrangements can often be made for this with the medical department of the nearest university.

The main thing, Naegeli reiterates, is the diagnosis, and this includes diagnosis by exclusion of simulation and exaggeration. Detection of these requires not only great medical knowledge and medical confidence but great psychologic talent, as the decision as to the simulation must be based usually merely on the physician's impressions. This is not enough for others, and this alone is enough to justify caution in affirming simulation. In dubious cases it is a wise plan to pass judgment on the man's condition only as it modifies his earning capacity. Although you do not assert that the man is malingering, yet you can report that his earning capacity is reduced very little if at all.

Naegeli warns of the necessity for extreme caution as to simulation in all cases in which there has been concussion of the brain, atheroma, multiple contusions and psychopathic factors. With hysteria, the complaints are constantly varying; the simulator sticks to his one trouble which is "always the same." With hysteria, the man is so convinced of his trouble that he is sure the physician will be convinced too, and he wastes no words trying to convince him, while the simulator keeps affirming the truth of his statements. The latter insists that he cannot be cured and makes no attempt to train himself to increase his earning capacity while the man with hysteria wants to be cured and rejoices at his progress. Mild hysteria and simulation are sometimes associated, and a tendency to a psychosis renders the whole problem more difficult of solution.

76. **Special Schools for the Deaf.**—Schlittler states that Basel opened last year three schools for children who are hard of hearing. All the children who could not hear a whisper at 6 feet were examined by a specialist. It was found that over three fourths of them had some curable ear trouble, and it was learned further that the hearing of about one fourth of all the supposedly normal children was somewhat impaired. Another significant discovery was that seven tenths of all the children in the classes for backward pupils had some ear disorder. In conclusion he reiterates the importance of seeking out and curing all curable cases of deafness, if for no other reason than to prevent such a loss to the military service when these children reach the military age.

between these different steps of the operation. If the tumor is not a cyst, he shells it out, working mostly from above downward. Usually these tumors are soft and friable. The field of operation is drained with gauze between the two sheets of the septum mucosa, the nostrils packed with cotton.

He keeps the passage down to the sella turcica permanently permeable by severing the right sheet of the septum mucosa at the back and above and fitting it against the left hand sheet of mucosa, thus leaving open the right nasal fossa, sphenoidal sinus and the cavity of the sella turcica. The tamponing must be firm; it is not needed after twenty-four hours. The septum is left thus attached only on the left side, but this does not seem to do any harm, the septum returning spontaneously to the middle of the cavity. It can be pushed aside at any time when the speculum is introduced to inspect anew the sella turcica region. In his last seven cases he refrained from the preliminary removal of the turbinate bones which is a cardinal point in the original Hirsch technic. By ample dilation of the nasal fossas with a dilator which he has had made for the purpose and describes with illustrations, he has been able to stretch the parts enough to admit the speculum. Of course the nose must be free from any inflammatory process, and he makes a point of giving hexamethylenamin systematically before and after the operation. He is careful not to resect the floor or the roof of the nasal fossas in order not to damage the architectural structure of the nose, and warns further that every step of the operation must be controlled by the eye, never working blindly in the depths, for fear of injuring the cavernous sinus. All the patients benefited materially by the operation, the success depending naturally on the nature and extent of the tumor and the stage of the pathologic evolution.

102. Cancer of the Thyroid.—Acute cancer and woody inflammation in the thyroid (Riedel's disease), may present such close resemblance that only microscopic examination of a scrap of the tissue will permit the differential diagnosis. Both occur generally in the thirties, and run a comparatively rapid course. A case is described in which, after a severe attack of grip, the temperature kept above normal and the neck enlarged, the enlargement settling finally in the thyroid region. The breasts also became very large and the patient felt weak and complained of palpitations, with edema over the upper part of the trunk. Necropsy revealed sarcoma of the thyroid with proliferation of the tumor into the veins and right auricle, reaching almost to the ventricle. The extent of this intravenous proliferation surpassed, it is stated, anything of the kind on record. The malignant disease ran its course in about three months, but there had been a tendency to goiter for fifteen years. It is reiterated that operative treatment of goiters which do not yield to medical measures is the only guarantee against malignant degeneration.

108 Heliotherapy and Thalassotherapy. F. J. Velez.—p. 78.

105. Amyotrophy of Articular Origin.—Cano quotes with approval Reclus' statement that it is a mistake to think that an arthritis is done with when the inflammatory symptoms have subsided. A train of functional disturbances are liable to follow, from simple slight reduction of function to atrophic paralysis. In his nine cases the extensor muscles and these alone became atrophied. His patients were from 17 to 30 years old, free from predisposing lead or alcohol poisoning or gouty taint. It is evident, he reiterates, that any joint lesion, however insignificant it may be, is liable to entail a grave and incurable affection. The irritation of the nerve terminals in the joint is responsible for it by a reflex mechanism, some of the cells in the anterior cornu of the spinal cord suffering. This irritation should not be aggravated by the use of the joint. It should be left in repose after the inflammatory phase is past. The muscles should not be forced into atrophy by violent contractions induced with strong electric currents. Electric treatment should be applied only by an expert who will use it cautiously. The surgeon should explain the conditions to the patient and warn of the probable prognosis. Further study is needed of these functional impotencies after joint disease, especially in connection with workmen's compensation.

111. The Blood Picture in Cubans.—Plasencia found in thirty-five healthy Cubans and in 1,000 specimens of blood from various patients that the reds numbered from four to six millions, thus not differing from the normal in latitudes farther north and in various races. The proportions of leukocytes and hemoglobin also keep within the familiar normal standards in health, but the relative leukocyte count shows exceptionally high figures for the polymorphous cells and the lymphocytes. The averages in fourteen men (and eleven women) were 56 (46.6) per cent. polymorphous cells; 5.2 (5.1) per cent. large mononuclears; 36.9 (36.1) per cent. lymphocytes; 2.5 (1.3) per cent. eosinophils, and 0.4 (0.5) per cent. mast cells.

112. Asphyxia from Medicolegal Standpoint.—De Castro emphasizes among the other features of death from asphyxia that the face and skin may present a normal aspect after death from asphyxia. The position of the head may lead to the mechanical subsidence of the primary congestion and cyanosis as the force of the circulation weakens. On the other hand, cyanosis may accompany death from other causes than asphyxia, and cyanosis often develops in the lower lying parts of the body after death. Visceral ecchymosis and congestion of the organs seem to be the most characteristic signs of asphyxia. The blood in the large vessels and right heart is generally free from clots, and sometimes in the left heart likewise. The oxygen in the blood may be down to 1.75 per cent. while carbon dioxid may be present up to 77 per cent. but there is no special sign, internal or external, peculiar to asphyxia as the cause of death.

126 The Fight Against Tuberculosis. C. Ferreira.—p. 678.

115. No Deaths from Smallpox at Buenos Aires.—The subtitle of Coni's article is "The Extinguishing of Small[illegible] [illegible] as he cites figures to show the diminishing tality. There have been a total of 11,459 deaths from smallpox at Buenos Aires since 1879, but in 1910 the figure dropped to 543, and to 1 each in 1914 and 1915, and none in 1916. No other Latin-American country can make such a showing, Coni remarks, and he ascribes this triumph to the efforts of Penna, chief of the public health service, hailing him as the paladin of the battle against variola.

116. **Pregnancy in Uterus Didelphys.**—The gravid cornu became twisted and the apoplexy of the uterus and placenta from the torsion compelled operative relief. Mazzini expected to find merely premature separation of the placenta with internal hemorrhage, having overlooked the spiral folds and crevices in the cervix which should have warned of the torsion. The parts had suffered and the gravid cornu and its adnexa were removed. Conditions seem propitious for future pregnancies as the half of the uterus left, with its adnexa, seem practically normal.

117. **Increasing Mortality from Tuberculosis.**—Coni reproduces recent vital statistics which show a constant increase in the tuberculosis mortality during the years of the war. The prevailing lack of work and scarcity of food are making their influence felt in this way. He remarks that the conflicts between capital and labor are assuming an alarming endemic character. He urges the state to interfere as the frequent strikes and threats of strikes are seriously undermining the general public health, as is evident in the tuberculosis mortality. Since 1877, the tuberculosis death rate had dropped from 28.1 per 10,000 to 15.8 in 1913, but it began to climb again with the war, and reached 19.3 in 1916 and has been even higher since.

118. **The "New Bacteriology of Tuberculosis."**—Castroman applies this term to Ferran's conception of the tubercle bacillus as the last link of a chain of mutations. He argues that this conception gives a promise of successful treatment by curing before the true tuberculosis stage is reached.

131 Flaccid Paralysis. G. C. Bolten.—p. 167.

127. **Atropin in Bradycardia.**—De Haas gives a description with tracings of a case of Adams-Stokes disease with sinus bradycardia in a man of 71. Although everything seemed to indicate that overexcitability of the vagus was responsible for the symptoms, doses of atropin up to 2.2 mg. had no accelerating influence on the pulse. Vagotony, therefore, cannot be responsible for the bradycardia in this case. The trouble, he declares, must be some obstacle to conduction between the sinus and the atrium.

128. **Plastic Correction of Saddle Nose.**—De Flines gives illustrations showing the excellent effect obtained in two cases of saddle nose by ingrafting a piece of bone to fit the place. It was taken with its periosteum from the tibia. Roentgenograms a year later show the bone implant of the same size and shape. It does not seem to have grown to the bone of the nose, but it shows no signs of absorption.

129. **Psychoses in Camp.**—Van der Hoeven relates that complete anesthesia of both halves of the body was found almost constantly in the several hundred soldiers that have passed through his service for nervous and mental disease. He found further that a large percentage of the men could have the cornea struck with the handle of a percussion hammer without the least trace of pain. There was lacrimation but no pain. Restriction of the visual field was common, and urticaria was easily induced by stroking the skin. He comments on the difficulty in the military environment of examining men with psychopathies. The commander assumes simulation whenever a man with normal temperature complains of symptoms, and it is a fact that now all the manifestations of disease are more or less influenced in the soldier by his distaste for military service and his longing to go home. Entirely opposite to the experiences in civilian circles, the mobilized Netherlands soldier more or less unconsciously strives to make the most impressive presentation of his symptoms. With all other forms of disability, the classification of the men as fitted for full duty, light duty, and capable only of manual work, has proved beneficial, but not so with the psychopathies.

132. **Improved Alcohol Sterilization.**—Christiansen's extensive research seems to have confirmed the hydrate theory of the action of alcohol—one molecule of methyl alcohol combines with 2 molecules of water; of ethyl alcohol with 4; propyl alcohol with 8; butyl alcohol with 16, and amyl alcohol with 32 molecules of water. The two latter alcohols are not very soluble in water and hence not practicable for sterilizing the skin, but propyl alcohol has numerous advantages over ordinary alcohol for sterilization as he explains in detail. It seems that alcohol makes its way rapidly into the cells when the superficial tension of about 0.4 is reached. Once inside the cells, the alcohol induces a kind of fixation, that is, in combination with the salt present in the bacteria it induces an irreversible precipitation of the protoplasm which signifies the death of the bacterium. Higher concentrations of alcohol do not have this effect but merely suck the water out of the protoplasm, which dries up the bacteria, but they are very resistant to drying. The power of alcohols to penetrate the thin layer of grease on the skin parallels their bactericidal power, as both are the effect of the same cause, namely, a low superficial tension and high solvent power for water and lipoids. And of all the alcohols, propyl alcohol is the most efficient, as he shows by his comprehensive tests on rat skin, human skin and ulcers. Its action compared favorably with that of iodin, phenol, and other powerful disinfectants, and he urges the general use of n-propyl alcohol as a disinfectant for skin and wounds. When pure it mixes freely with water. Mixed with three times as much water, the superficial tension is 0.4.

TREATMENT OF ACUTE INFECTIONS OF THE JOINT BY LAVAGE AND DIRECT MEDICATION

JOHN W. CHURCHMAN, M.D.
Professor of Surgery, Yale University School of Medicine
NEW HAVEN, CONN.

Since the publication of a paper[1] in 1915 in which a new method for the treatment of acute infections of joints, particularly of the knee joint, was described, I have been interested in the further development of the apparatus devised for this purpose and in the collection of further clinical data as to the efficiency of the method. The rather crude machine described in my first article answered the purpose well, but there were a number of mechanical defects in it, and these made it somewhat awkward. These defects have been entirely overcome, and an apparatus that is simple and efficient has now been devised, so that the problem of thorough irrigation and cleansing of a joint cavity is solved.

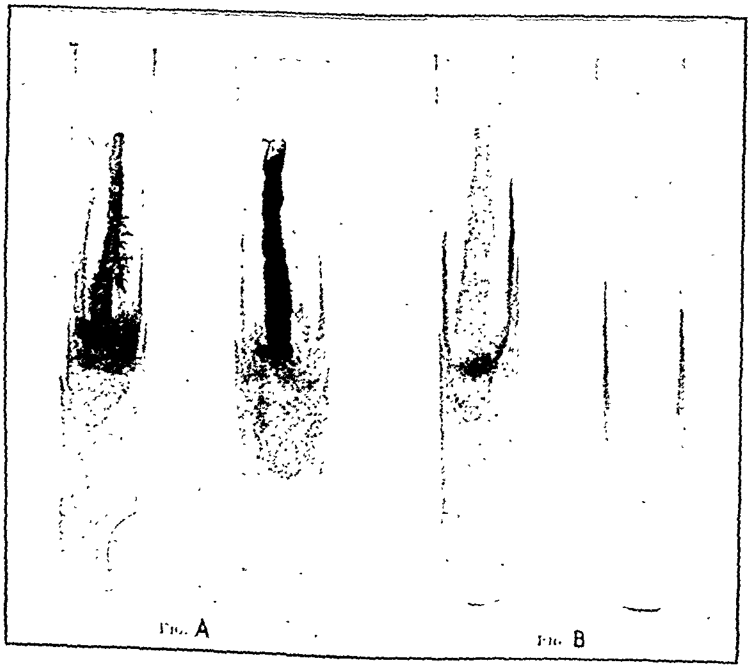

FIG. A FIG. B

Fig. 1.—Effect of staining organisms with gentian violet: Gram-negative organisms are unaffected, gram-positive organisms are killed. *A*, tube on left inoculated with Bacillus prodigiosus (gram-negative) for control; tube on right with B. prodigiosus that had been stained one hour with gentian violet. The growth of the stained organisms has been unaffected by the dye. *B*, same experiment with B. subtilis (gram-positive). Tube on left inoculated with B. subtilis for control; tube on right with B. subtilis that had been stained for one hour with gentian violet. The growth of B. subtilis has been stained for one hour with gentian violet. The growth of B. subtilis has been completely inhibited by the dye.

As I stated in my former article, any attempt to apply an antiseptic to the lining membrane of a joint, with the hope that this substance would reach and penetrate cells of that lining, is sure to be unsuccessful unless a prelminary cleansing has been effectively carried out. My attention was called to this fact by my complete failure to stain the mucosa of the pharynx by painting it with gentian violet, because the secretions of the mucous glands of the pharynx covered the surface with a thin slimy layer, which was renewed by fresh secretions as rapidly as it was removed, and which prevented intimate contact between dye and mucous membrane as effectually as a layer of grease would have done. It seemed to me likely that the pus, fibrin and mucus accumulating on the surface of a synovial membrane must certainly interfere in a similar, and equally decisive, fashion with any attempts to apply to its surface a diffusible antiseptic.

The apparatus described herein is the result of attempts to devise some method by which an infected joint can be first mechanically cleansed with complete thoroughness, so that diffusible antiseptics applied to the joint may then come actually into contact with the cells of the synovial membrane. Repeated trials of the apparatus to be described have proved that a mechanical cleansing of this sort may be done with great readiness under local anesthesia. I wish to consider also the attempts to make clinical use in infected joints of the observations as to the bactericidal value of gentian violet, to which attention was first called[2] in 1912, and to the study of which several other papers during that and subsequent years were devoted. It is hardly necessary to repeat in detail what those findings were, for in the first paper[1] I summarized them. Suffice it here to say that a selective bactericidal property was found to be possessed by gentian violet; that this selective property ran roughly parallel with the gram reaction; that the property was exhibited by the dye either when the dye was applied directly to the bodies of the organisms or when it was applied to the medium in which they were grown (Figs. 1, 2 and 3); that it was manifested in extremely weak solutions, and that it was shown to be a vital phenomenon, since living cells stained with the dye continued to grow.

---

[2] Churchman, J. W.: The Selective Bactericidal Action of Gentian Violet, Jour. Exper. Med., 1912, 16, 221.

In addition to these studies on gentian violet itself, subsequent studies also were reported on a similar action possessed by stains closely allied to gentian violet, and it was shown in these that the selective property was common to a number of stains closely related in chemical structure. Experiments were reported as having proved that the dye possessed a relatively low degree of toxicity, and it was also shown that the dye possessed the power of staining living cells. This was proved, first, by cultural experiments, in which a small amount of gentian violet was added to the medium in which epithelial tissue was growing; it was shown that the cells picked up the dye (both their bodies and nuclei being stained with it) and that, in spite of this fact, cell division continued. That the dye possessed the power of staining living cells was also shown by a number of experiments on animals in which the bladder of the living animal was filled with the dye; on removal of the organ, the mucosa was shown to be stained throughout its depth.

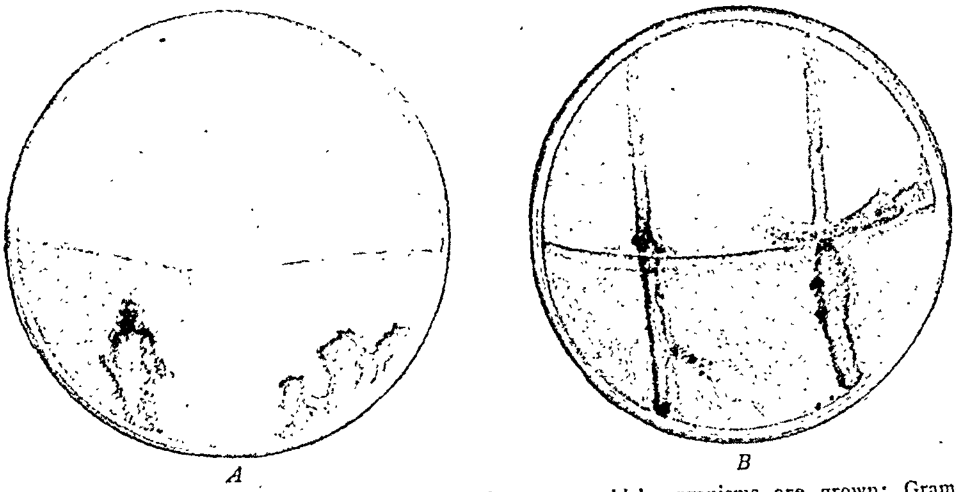

Fig. 2.—Effect of gentian violet in the mediums on which organisms are grown: Gram-positive organisms will not grow in the presence of the dye; gram-negative organisms grow as well in gentian violet as in plain agar. The lower half of the Petri dish in these two illustrations contains plain agar; the upper half, agar to which gentian violet (1: 100,000) has been added. *A*, an emulsion of Sarcina rosea (gram-positive) has been streaked across the plate. The organism grows well in the plain agar, but does not grow at all in the gentian violet agar, growth ceasing some distance before the dividing line is reached. *B*, an emulsion of B. prodigiosus (gram-negative) has been streaked across the plate. Growth of the organism occurs in the plain agar and on the gentian violet agar with equal profusion.

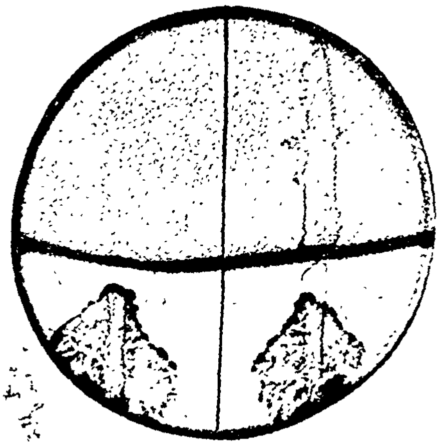

Fig. 3.—Selective action of gentian violet on a mixture of gram-positive and gram-negative organisms: A divided plate, the upper half containing gentian violet agar and the lower half plain agar. The left half of the plate has been stroked with a mixture of Bacillus subtilis and Micrococcus aureus, both gram-positive; the luxuriant growth in the plain agar ceases some distance from the dividing line, and there is no growth whatever in the gentian violet agar. The right half of the plate has been stroked with the same mixture plus B. typhosus (gram-negative). At the point where the growth of B. subtilis and M. aureus ceases, a pure culture of B. typhosus is seen crossing the line and growing well in the gentian violet agar.

I wish to report the application of the apparatus thus devised, and the knowledge as to the bactericidal property of a dye capable of staining living cells without doing them any apparent damage, to the treatment of suppurative infections of the joint; for it seemed to me that joint infections of this kind presented the best point of attack in making practical application of the bactericidal observations which I have published. The studies have thus far been confined to the knee joint, first because this is the joint most easily aspirated and irrigated, and second, because, though a sharp lookout has been kept for suitable cases, the fairly active service of the New Haven Hospital has provided me no suitable infections in other joints. I have, indeed, been surprised to find that suppurative infections of the knee are much less common than I had supposed.

APPARATUS AND METHOD

The apparatus (Figs. 4, 5 and 6) consists essentially of a series of interconnecting chambers leading ultimately to a single tube, *F*, which is attached to an aspirating needle for insertion into the joint. The apparatus is connected also with another single tube, *G*, leading from a to-and-fro pump. By means of properly arranged valves and stopcocks it is possible to blow or suck fluid into or out of the joint and also from or into any one of the connecting chambers of the apparatus. The system is an entirely closed one, and there is therefore no danger of contamination of the joint from without; the air from the pump passes through a sterilized cotton filter. The essential parts of the apparatus may be readily seen in the illustrations.

The whole apparatus will fit into an ordinary autoclave, and may be sterilized with the chambers containing the fluids to be used; Chamber *I* contains gentian violet; Chamber *E*, salt solution; and Chamber *D*, 2 per cent. procain (novocain). These fluids are introduced by the removal of Cap *K* and the turning of Stopcock *L* into the proper position. The irrigation and treatment of the knee are done under local anesthesia; it is a simple procedure and practically painless. The skin is anesthetized, either at the inner or outer surface of the joint, and the trocar inserted into the joint. It is quite essential that a trocar as large as the one illustrated be used (Fig. 7), for large quantities of fluid must have thorough access to the joint, and one must also be able to suck out of the joint bits of mucus and fibrin that may be there. In my first cases I was rather fearful that the use of such a large trocar might lead to the formation of a permanent sinus; but there seems to be no danger whatever of this, as the puncture hole closes almost immediately.

After the needle is inserted, Stopcock *A* is turned into proper position, suction applied, and the contents of the knee joint run into Chamber *B*. By the turning of Stopcock *A* and application of pressure through the pump, this fluid is then forced through Tube *C* into a flask, to be preserved for study. Stopcock *A* is then put in the proper position, pressure applied by the pump, and the procain is driven from Chamber *D* through Tube *F*, into the knee, in sufficient quantity to distend it. This is left in the knee for a few moments and again withdrawn (by the turning of

Stopcock *A*) into Chamber *B*. Salt solution is now allowed to run from the containing Chamber *E* into Chamber *D* by turning Stopcock *J;* and then, by turning Stopcock *A* into the proper position and applying pressure on the pump, the salt solution is forced into the joint to complete distention. It is then sucked out into Chamber *B*. This is repeated until the salt solution returns clear. Chamber *D* is then filled with hydrogen peroxid by turning Stopcock *A* and applying suction, which draws the fluid from a stock bottle through Tube *H* into Chamber *D*. This peroxid is then forced into the joint just as the salt had been, and is again withdrawn. The joint is then washed out again with salt solution. After this process has been repeated, the fluid will return perfectly clear, and one may feel sure that the knee joint is now clean of pus, mucus and fibrin. Gentian violet, 1:1,000, is now allowed to pass into Chamber *D* from retaining Chamber *I* by turning Stopcock *J;* and is then forced into the joint, as the saline and hydrogen peroxid have been, to the point of distention. This dye is left in the joint for five minutes, at the end of which time one can feel reasonably certain that the synovial membrane has been thoroughly stained. It may then be withdrawn and a small amount of weaker dye, 1:10,000, introduced.

If the results within the knee are at all parallel to the results obtained in the bacteriologic laboratory, one is justified in assuming that after the mucus, fibrin and pus have been got rid of by mechanical cleansing, the stronger solution of gentian violet kills organisms lying loose within the joint, on the surface of the synovia, or in its depths; and that if certain organisms do escape this dye, their development must be retarded by the presence of a weaker solution of the dye in the medium in which they are growing. This is the reason why strong dye is first used to stain the synovia, and a smaller amount of weaker dye left in the joint. After the dye has been introduced in this manner, the needle is withdrawn, a small piece of dry gauze placed over the puncture hole, and a pressure bandage of flannel applied. If there are indications that another irrigation and staining are necessary, the process can be repeated very readily at the end of a few days.

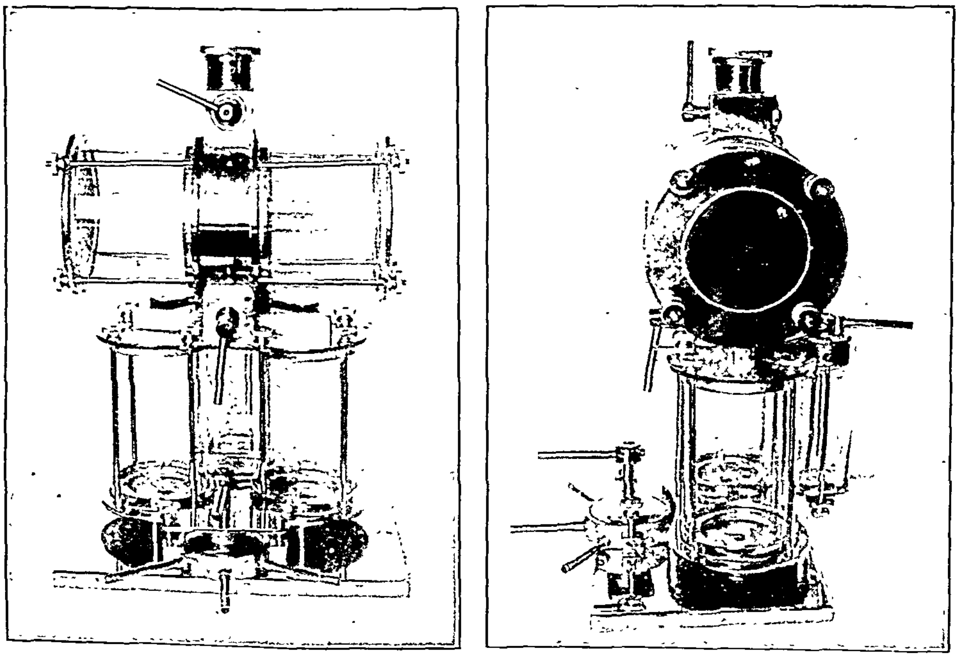

Fig. 4.—Front and side views of apparatus for irrigation and lavage.

RESULTS OF TREATMENT

By the method just described, a series of infections of the joints, all of them infections of the knee, have been treated in the New Haven Hospital. The number of cases in this series is not large, but certain of them offered such excellent opportunity for the study of the effect of the method of lavage and staining that they may be regarded as crucial experiments. The first point that struck me in these cases was the ease with which a joint could be not only washed out but also distended with no pain, or at most, a very slight amount. This was contrary to my expectations, as the pain of joint effusions is usually thought of as associated with distention and based on it; but there is no question at all that a joint can be distended to its utmost capacity with very slight pain, and if a simple local anesthetic is used there is no pain. The studies have also proved, what my experimental work had led me to expect, that gentian violet can be used in strong solutions applied to the surface of synovial membranes without the slightest damage. I had not been prepared to find that there would be no symptoms of irritation whatever, but this is in fact the case.

The series of cases treated contains eight infections of the knee, two of them pyogenic, five gonorrheal, and one of unknown character, probably tuberculous. It is Cases 7 and 8 to which I wish to call special attention, for the first six were done during the time when the apparatus for irrigation was being developed, and the cases themselves were not as carefully studied as later cases. In spite of this fact there were complete cures in Case 1, in which there was a purulent effusion of the knee which was entirely cured by one or two irrigations. The same is also true of Cases 2, 3 and 4. Particularly instructive was Case 2. This patient suffered from a double gonorrheal arthritis of the knee, with the usual golden effusion, and he was completely relieved of all signs and symptoms. In Cases 7 and 8, however, the effect of the treatment was controlled not only by clinical observations but also by roentgen-ray and bacteriologic studies.

CASE 7.—A boy entered the hospital with an acute pyogenic infection of the left knee, following a slight wound of the lower leg. It was impossible to do the operation under local anesthesia, as the boy was difficult to control and became unmanageable on entering the operating room. Primary ether anesthesia was therefore given. The fluid withdrawn from the joint was thickly purulent. It contained staphylococci on smears, and a pure culture of *Staphylococcus aureus* was grown from it. The joint was irrigated with salt solution and then stained with 1:1,000 gentian violet in the manner described. A small amount of 1:10,000 gentian violet was left in the joint. Five or six days later the operation was repeated. At this time the fluid withdrawn from the knee was normally limpid synovial fluid, very slightly stained with gentian violet, and the cultures made from this fluid were negative. The washings and stainings were repeated. The clinical symptoms promptly disappeared, and the boy had a normal knee when he was discharged, except that the tissues about the knee were still slightly swollen. The motions were normal; both flexion and extension could be actively carried on to completion.

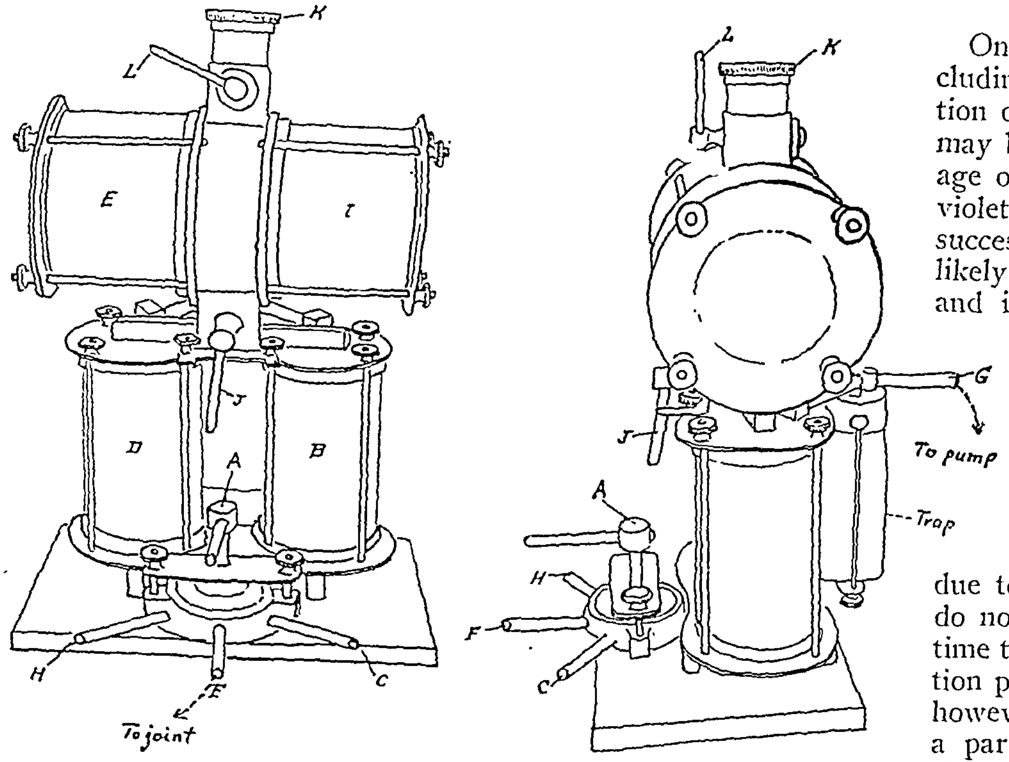

Fig. 5.—Outline of views illustrated in Figure 4.

Case 8.—The condition was one of gonorrheal arthritis of the left knee. The clinical picture was quite typical, but the symptoms were less acute, as regards extreme tenderness, than is usually the case. The operation was done under local anesthesia. At aspiration the usual golden yellow fluid, containing fibrin clots, was withdrawn. A gram-negative diplococcus was found in the smear. These organisms could not be grown in culture. The knee was washed out with salt solution, after which it was stained with 1:1,000 gentian violet. The clinical symptoms promptly subsided, and the boy regained complete use of his knee in a short time.

APPLICATION OF THE TREATMENT IN EIGHT CASES

Case and Joint	Diagnosis	Roentgen Ray Findings	Character of Effusion	Smear		Culture		Function	
				Before	After	Before	After	Before	After
1. Knee	......	......	Purulent	.....	......	.....	..	Restricted	Good
2. Knee	......	......	Gonorrheal	.....	......	.....	..	Restricted	Good
3. Knee (double)	......	......	Gonorrheal	.....	......	.....	..	Restricted	Good
4. Knee	......	......	Gonorrheal	.....	......	.....	..	Restricted	Good
5. Knee	......	......	Gonorrheal (old)	.....	......	.....	..	Restricted	No improvement
6. Knee	......	......	Tuberculous (?)	.....	......	.....	..	Restricted	Slight improvement
7. Left knee	Septic	Negative (slight irregularity joint surface)	Purulent	Staphylococci	Limpid synovial	Pure staphylococcus aureus	Neg.	Marked limitation	Normal
8. Left knee	Gonorrheal	Negative	Golden yellow serum with fibrin clots	Gram-Neg. diplococci	Only 1 treatment	Sterile	..	Marked limitation	Normal

In both of these cases the roentgen-ray studies showed no definite bone changes, though there was possibly some periosteal thickening in Case 7.

COMMENT

One is justified, I think, then, in concluding that apyogenic or gonorrheal infection of the synovial membrane of the knee may be cured simply and promptly by lavage of the joint and staining with gentian violet. It is probable, of course, that the success of this treatment would be less likely the longer the process had continued, and it should hardly be necessary to say that no hope should be entertained that, if bone lesions are present, these can be influenced by the treatment. The question, of course, at once arises whether the gentian violet used played any part in the results obtained, or whether the cure of the condition was simply due to thorough cleansing of the joint. I do not think any data exist at the present time to make a positive answer to this question possible. It seems to me rather likely, however, that the gentian violet does play a part, for I have shown experimentally that gentian violet kills with great ease gram-positive organisms, and that it prevents the growth of gram-positive organisms when present in weak dilutions. It also prevents the growth of gram-negative organisms when used in strong dilutions. I have also shown experimentally that this stain, if applied to the surface of a mucous membrane, reaches its depths. It seems to me reasonable to suppose that in these cases of purulent synovitis the organisms lying on the surface or in the depths of the synovial membrane are killed by the stain used, provided the surface of the membrane has first been subjected to a thorough mechanical cleansing.

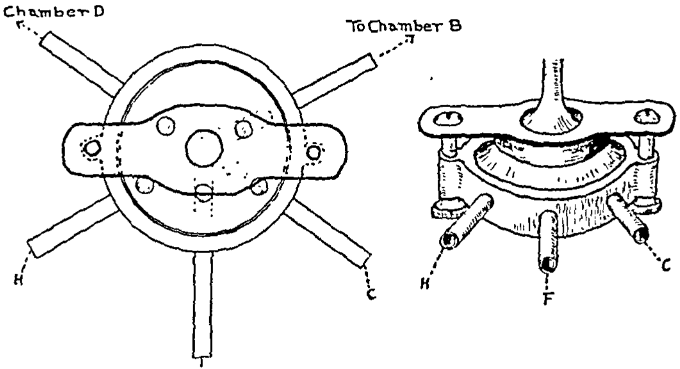

Fig. 6.—Detail of valve leading to tubes H, F and C, and controlled by Stopcock A.

It is evident that these findings open up possibilities for the treatment of other confined infections. For example, I am now working on the treatment of abscesses near the surface, which I hope to aspirate, irrigate, and stain in the same way, and it is my intention also to see if this sort of treatment cannot be applied to other cavities, particularly to the pleural cavity, and to the pelvis of the kidney.

The apparent success of the use of gentian violet in this manner has also led me to attempt to use it in a somewhat different fashion, namely, by actual injection into the tissues themselves. Here, of course, I have had to proceed with the greatest possible care, first testing out on animals and on certain individuals who offered themselves for this purpose the irritating effect of the dye when thus injected. There is no doubt that it is slightly irritating when injected directly into the tissues. The pain of this irritation can be completely overcome by dissolving the dye in 2 per cent. procain solution instead of in salt solution; but even when this is done, if the dye is used in solutions as strong as 1 : 1,000, there is some danger that it will lead to necrosis. I am not sure whether this necrosis is entirely due to the dye itself or to the distention, for I do not think sufficient care was used in these experiments to rule out the possibility of necrosis due to distention. The experiments went far enough, however, for us to begin the study of treatment of infections by direct injection of the dye into the tissues, and I selected for this purpose the treatment of pyorrhea alveolaris. A few severe cases of this disease have been under treatment by Dr. Gompertz of New Haven, who, under my direction, has been injecting weak solutions of gentian violet in procain directly into the gum about the pus pockets at the roots of the teeth. These studies have gone far enough to allow us to say that injections of this sort may be made without pain and with impunity. The results in these cases I have not been able to control as well as I wished, and it is too early to draw any positive conclusions. They have at least been encouraging, and in one of the cases were quite striking; for this patient, who had been suffering for a long time with pyorrhea alveolaris and had been advised by a very good dentist that the only hope for her was to have all her teeth removed, has been relieved of practically all her symptoms and still has her teeth. I think, however, that we are not justified in saying more than that this method of treating infections is promising.

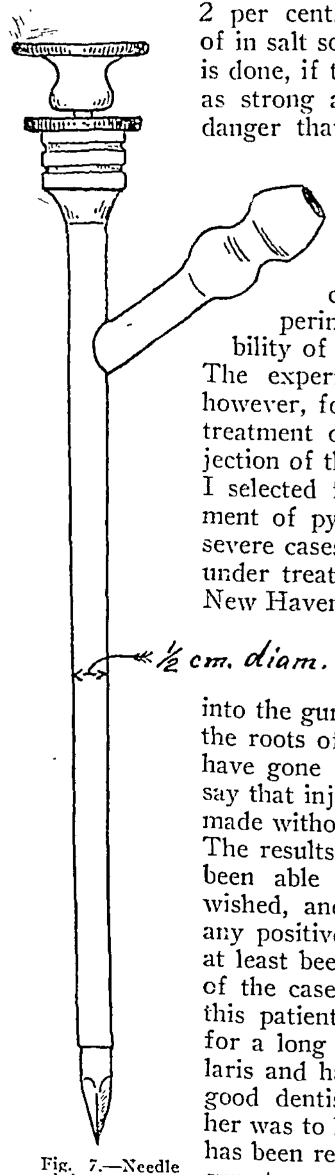

Fig. 7.—Needle used in lavage of the joint, illustrated to emphasize the need for using a needle of large caliber.

I am also studying the effect of staining, with gentian violet, skin infected with parasitic diseases, with the hope that the application of this stain to the surface and its injection under the surface may render the tissue so hostile to parasitic growth as to conquer the infection.

THE TREATMENT OF CANCER OF THE LIP BY RADIUM

A REPORT OF TWENTY-FOUR CASES

HENRY H. JANEWAY, M.D.

NEW YORK

Epithelioma of the lip offers favorable conditions for successful treatment, whether by operation or by radium, more frequently than the majority of other forms of epidermoid carcinoma. This circumstance depends, not on less malignant tendencies, but rather on the exposed position of cancer of the lip. A malignant new growth of the lip excites the concern of a patient in a far earlier stage than the same kind of growth inside the mouth. For this reason, patients having cancer of the lip with great regularity seek assistance when their growth is still small and superficial. In these stages cancer of the lip offers particularly favorable conditions for successful treatment by radium. The growth is most accessible and can be completely covered by radium. If it is justifiable to treat any form of early cancer by radium instead of by operation, it is cancer of the lip.

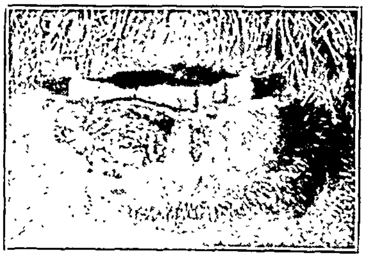

Fig. 1 (Case 2).—Before treatment, Feb. 21, 1917.

In the report[1] on radium therapy in cancer at the Memorial Hospital for 1915-1916, the results in the treatment of six patients with early cancer of the lip were published. In four of these patients the disease was superficial, but two had considerable submucous infiltration of the substance of the lip. One of these patients (one of the four with the more superficial cancer) has not been traced to date. When last seen his lesion had entirely disappeared, and the lip appeared normal.

The remaining five have been traced to Jan. 1, 1918. In one of them a recurrence has developed. This patient (N. N., Hospital No. 22251) was one of the two with considerable submucous infiltration of the lip. He received his single radium treatment, July 7, 1915. The recurrence developed two years later in the cervical lymphatics, and only his infirmity (he is now 77 years old), rendering him unable for the past few months to leave his home, has been responsible for the failure to remove these glands. He still has no local recurrence, and had it been possible to dissect out the glands in the neck at an early period, it is possible that he would still be free from disease.

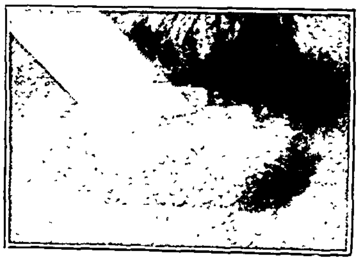

Fig. 2 (Case 2).—After treatment, Feb. 18, 1918.

The remaining four patients are still free from disease. These patients were first treated as follows:

---

[1] Janeway, H. H.: Radium Therapy in Cancer at the Memorial Hospital, New York (First Report: 1915-1916), New York, Paul B. Hoeber, 1917; The Action of Radium on Cancer, Surg., Gynec. and Obst., 1918, **26**, 233.

G. MacK., Nov. 15, 1915; R. O'C., Jan. 27, 1916; F. L. (Hospital No. 22980), March 14, 1916, and C. C. (Hospital No. 23827), Oct. 20, 1916. The full description of lesions and the histories of these patients, with the dosage they received, will be found in the report referred to.

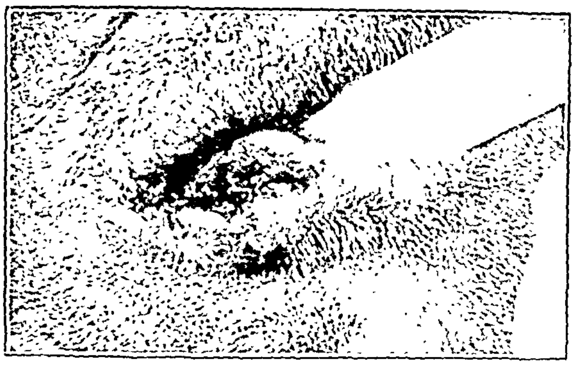

Fig. 3 (Case 5).—Before treatment, May 31, 1917.

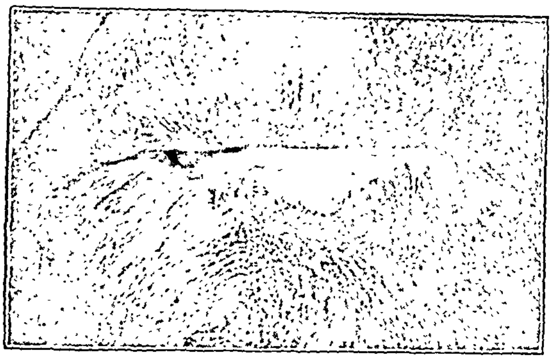

Fig. 4 (Case 5).—After treatment, Sept. 20, 1917; no induration remaining.

During the past year we have treated eighteen additional cases of epithelioma of the lip with radium. The immediate result has been as favorable as in the first series of cases reported. As we are attempting to do in the six cases of the previous report, we hope to publish the end-result of all cases later. A microscopic confirmation of the diagnosis was obtained in only a few of the patients in whom it could be made without serious inconvenience to them. The macroscopic appearance of all these lesions was typical, and the diagnosis in each case was confirmed by several observers at the weekly consultation of the attending staff of the hospital. We considered it unjust to subject these patients to the trauma of a removal of a piece of tissue for section purposes merely to meet the criticism of the incredulous.

The microscopic determination of the degree of invasion of the substance of the lip, as Bloodgood has shown, is not of much importance from the standpoint of the ultimate course of the lesion, as all the cases of well established cancer have passed through an early stage indistinguishable from the superficial lesions.

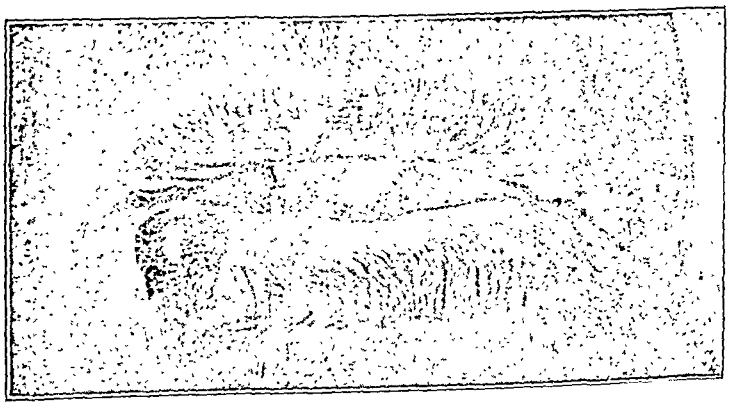

Fig. 5 (Case 6).—Before treatment, June 15, 1917.

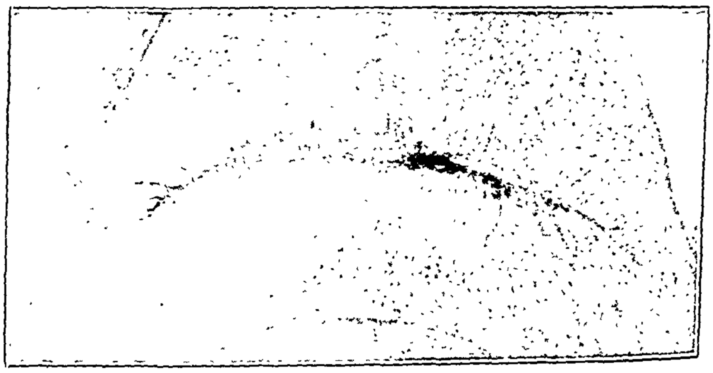

Fig. 6 (Case 6).—After treatment, Feb. 11, 1918.

Of the twenty-four cases in this report, eight were judged to be superficial early cancerous lesions, without deep invasion of the muscle. Sixteen were well established cancer, with unquestioned deep invasion of the tissues of the lip. As might be expected, there were no therapeutic failures among the eight superficial lesions.

Of the whole series of twenty-four cases, twenty-three patients were men, only one being a woman. All but one were carcinomas of the lower lip. The single case of cancer of the upper lip was in a man.

The average age was 54. The youngest (Patient 11) was 38. The oldest was the woman (Patient 15), aged 84, the next oldest (Patient 1) being 78 years of age. The most frequent etiologic factor seemed to be tobacco, all patients except the woman admitting the use of tobacco in generous amounts.

In only one patient was syphilis admitted. In two patients (22251 and 24492 [Patient 6]), direct trauma seemed to be a factor. In one of these the trauma was caused by the chronic irritation produced by the ragged edge of a decayed tooth. In the other patient the injury to the lip was produced by an oyster shell during eating.

DURATION OF LESION BEFORE TREATMENT

Number of patients	Duration Before Our Treatment
3 (1 early cancerous)	From 1 to 3 months
5 (1 early cancerous)	From 3 to 5 months
2	From 6 to 12 months
7 (1 early cancerous)	From 1 to 2 years
3 (all early cancerous)	From 2 to 3 years
2 (both early cancerous)	4 years
1	8 years
1	12 years
24 (8 early cancerous)	

The duration of the lesion before the patients came to us for treatment is of much interest. This period averaged thirty months, the shortest time being one month, and the longest twelve years. The cases may be classified, with regard to duration, as in the accompanying tabulation.

The duration of the disease before treatment, apart from the character of the growth, has little bearing on the prognosis. Two of the eight early cancerous lesions were stated to have begun to develop four years before treatment, and some of the most malignant had a short period of growth before treatment. The rapidity of growth and size of the lesion are the all important factors determining the malignancy and affecting the prognosis. A long pretreatment history does not necessarily indicate a benign lesion. The critical factor is the rate at which the lesion is growing at the time of treatment. Many lesions that are stated to have begun months or years before suddenly start to grow rapidly a short time before the patients come for treatment. In fact, it is usually the increased activity of the lesion that alarms the patient. Such increased activity on the part of the growth probably marks the transition between the localized cancerous stage and the true infiltrating cancer.

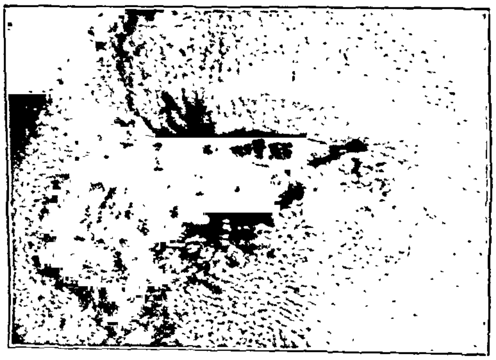

Fig. 7 (Case 12).—Before treatment, Oct. 2, 1917.

It is of much importance to recognize what constitutes a beginning or early cancerous lesion of the lip, and that such lesions uncured have all the potential life-destroying power of established cancer. This stage is the most favorable time in which to treat cancer. No more important progress in the therapeutics of cancer could be made than so improving both diagnostic methods and the education of the public that a larger and larger proportion of patients can be treated in the early stage. It is a stage easily recognized on the skin and lip, less easily inside the mouth, where the surfaces are moist and more hidden, and almost impossible of detection in many other locations. It nevertheless should be the aim of medical science to accomplish the treatment of cancer in this early stage.

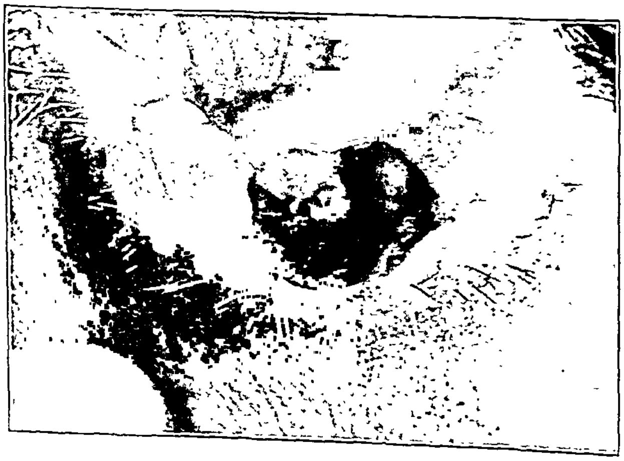

Fig. 9 (Case 13).—Before treatment, Oct. 11, 1917.

It is the stage above all others in which radium can be counted on to be successful, a remedy toward which patients will not hesitate to turn, as they so often avoid the knife.

When it has once been definitely established, it is only under the rarest circumstances that the removal of some chronic source of irritation will cure a beginning cancerous lesion. Such removal of chronic sources of irritation may be successful in the incipience of the growth, and in any case should always be insisted on as an important contributory factor to whatever therapeutic measure is employed.

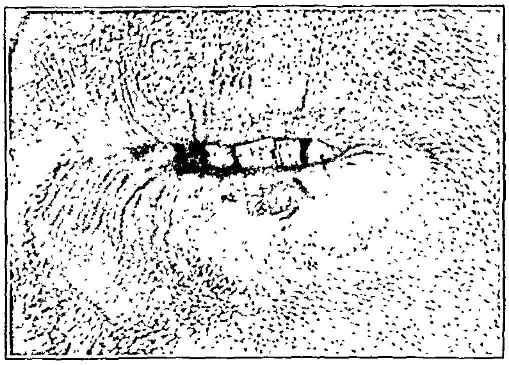

Fig. 8 (Case 12).—After treatment, Feb. 18, 1918; ulceration practically healed; all induration absent.

In the stage of which we are speaking, as is also often the case in well established or even advanced cancer, a single treatment in experienced hands will produce a cure. In fact, in our cases the best results have followed single treatments.

With the exception of three cases (4, 13 and 14) now under treatment, in all of which the patients are at present doing well, although the ultimate prognosis is doubtful because all three patients had advanced lesions when they applied for treatment, and Case 1 in which the patient had developed multiple glandular metastases at the time treatment was begun, and another patient with a very extensive local disease involving the whole of one cheek (Patient 10), all patients have been healed, and are now free from evidences of their disease.

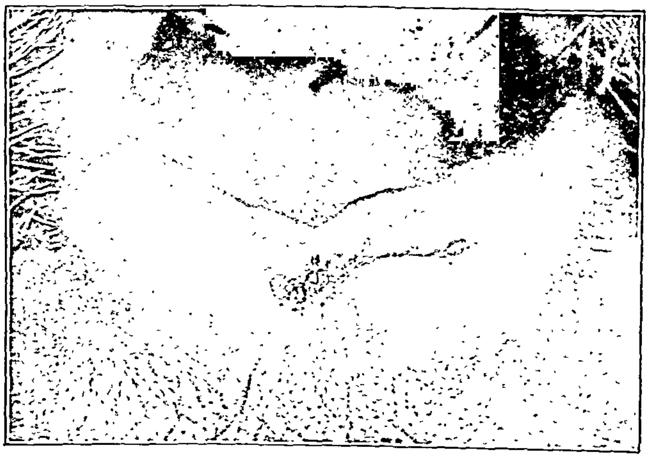

Fig. 10 (Case 13).—After treatment, Feb. 18, 1918.

Although the real value of these results will not be settled until a number of years hence, yet if radium is found to be a reliable therapeutic agent in cancer of the lip, it possesses obvious advantages over excision in the treatment of early and therefore superficial cancer. One of the most important of these is the fact that it attacks the disease from the surface, and therefore in the direction of its shortest diameter. It saves the patient the unnecessary sacrifice of large amounts of healthy tissue, at the same time not incurring the danger that comes from an excision by a division of the tissues too near to the margin of the disease.

A number of our cases (as 8 and 2) well illustrate the tendency for early cancer of the mucous membranes to spread for some distance on the surface, often far beyond the usual place of excision. Such extensions, although still remaining quite superficial, may have healthy bridges of mucosa between them and the primary starting place of the disease.

We regard the lymphatic extension as embolic, and believe that the cervical lymph nodes perform for a time a conservative function. Obviously enlarged nodes should be removed by clean dissections, after the primary disease has been treated, but if possible not before definite retrogression has been obtained by radium treatment. The early dissection of the triangles of the neck, involving as it often does the sacrifice of normal lymphatic glands, may actually be harmful by removing Nature's barriers and cutting across lymphatic trunks which, if left unsealed, may now drain fresh cancerous emboli into the closed wounds of the neck. In our experience many an unnecessary operation has been saved by delaying the operation on the regional lymphatics until there were definite indications for performing it. No harm has resulted from this delay when patients have been able to obey instructions. Possibly there is less danger of lymphatic extension when the primary disease is treated by radium than when it is excised.

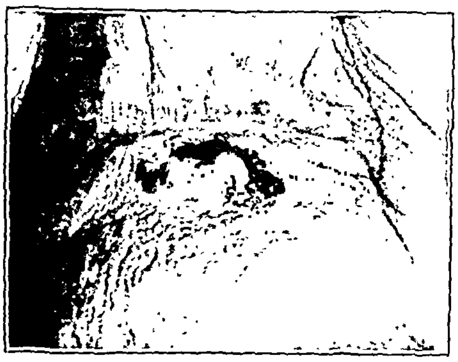

Fig. 11 (Case 15).—Before treatment, Dec. 3, 1917.

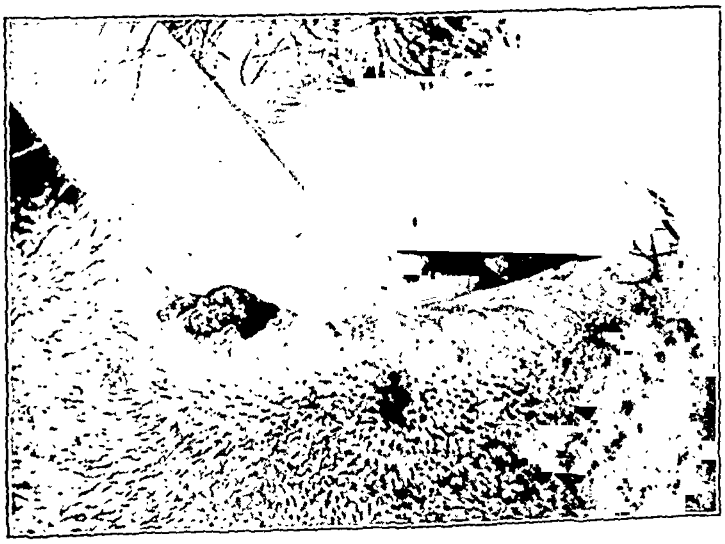

Fig. 12 (Case 18).—Before treatment, Dec. 18, 1917.

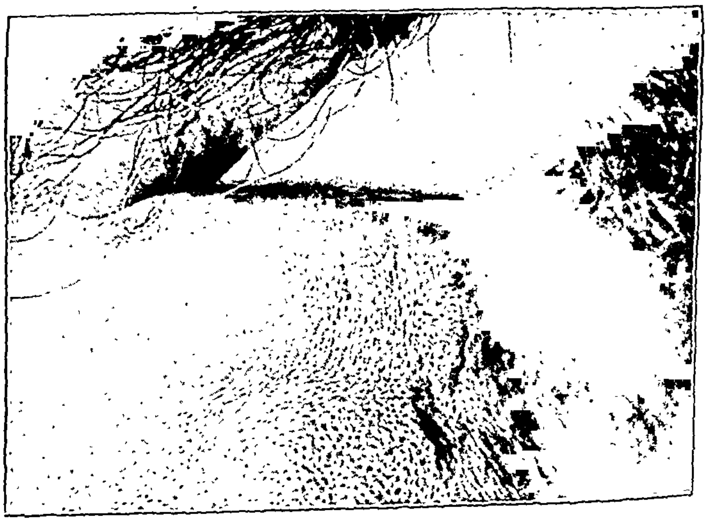

Fig. 13 (Case 18).—After treatment, Feb. 1, 1918.

When neck dissections are performed, we believe that it is an additional safeguard to place radium in the wound against the amputated stump of lymphatic channels descending from the primary lesions.

REPORT OF CASES

The following is a brief summary of the case reports of the second series of cases of epithelioma of the lip treated during the past year at the Memorial Hospital:

Case 1 (Hospital No. 24106).—P. T., man, aged 78, married, with children, admitted, Jan. 23, 1917, had had the vermilion border of the right half of the lower lip in part destroyed by an ulcer 2.5 cm. in diameter. The base and edges were hard, and the latter rolled out. There was considerable deep infiltration of the substance of the lip. The lymph glands in both submaxillary and submental spaces were enlarged. Those in the right submaxillary space formed a tumor 5 cm. in diameter at its base. The pathologic diagnosis was epidermoid carcinoma.

The lesion on the lip had first been noticed three years before. Four months before it had first been treated and temporarily improved by an electric needle and four roentgen-ray treatments. The patient had been a heavy smoker. He denied syphilis, and did not indulge in alcohol.

Jan. 23, 1917, 300 millicuries, in twelve tubes of rubber-covered 1 mm. platinum, were applied for one hour.

March 7, not much improvement was noted.

March 12, 240 mc., in twelve tubes of rubber-covered 1 mm. platinum, were applied for two hours on the lip; 1,200 mc., in 2 mm. lead, were placed over the tumor in the neck for six and a half hours.

April 24, there was no change in the tumor of the neck; but the ulcer on the lip was much improved, although there was still much induration left.

May 13, under local anesthesia, the ulcer on the lip was excised with the actual cautery, and the lymph nodes in the submaxillary and submental spaces were removed. It was also necessary to remove a portion of the lower jaw that had been invaded by the glandular tumor of the neck. Eight tubes of rubber-covered 1.5 mm. of platinum, containing 45 mc. each, were inserted into the wound of the neck, and left in place for two hours.

July 11, the patient returned with an extensive recurrence in the deep cervical glands of the right side of the neck. An attempt to remove them completely was unsuccessful, as the capsule of the glands had been penetrated by the disease.

November 14, the ulceration had reappeared over the place where the jaw bone was resected, and a hopelessly extensive recurrence had developed in the tissues under the incision through which the glands on the right side of the neck were incompletely removed.

Jan. 16, 1918, the patient died.

Case 2 (Hospital No. 24159).—T. K., man, aged 48, married, with two children, a motorman, admitted, Feb. 12, 1917, had an ulcer 2.5 cm. in diameter, on the right half of the vermilion border of the lower lip. In its center, the ulcer was crossed by a vertical scar. The ulcer was superficial, but the substance of the lip beneath its base was indurated to a considerable depth along the scar. There were no palpable lymph nodes. There was a bilateral lupus erythematosus on the face and nose.

The lesion had first been noticed six months before as a pea-sized blister just to the right of the middle line. One week before a wedge-shaped piece had been removed at a dispensary for microscopic examination, and was found to be epithelioma. The patient smoked about one paper of tobacco a week in a clay pipe. He denied syphilis and indulgence in alcohol. His teeth in the neighborhood of the lip showed no jagged, decayed edges, though they had not been kept clean.

Feb. 12, 1917, 280 mc., in eight rubber-covered 1 mm. platinum tubes, were applied for one hour.

May 2, there was no evidence of disease present.

September 27, a new ulcer, with characteristically indurated base and edges, 0.75 cm. in diameter, covered with a coblike scab, had developed on the opposite (left) side of the vermilion surface of the lip. Still no enlarged lymphatics were palpable in the neck.

September 28, 63 mc., in three 0.5 mm. silver tubes, were applied over an area of 3 sq.cm., in dental compound, three hours.

October 9, the lesion treated had disappeared.

Jan. 11, 1918, there was no evidence of disease.

Case 3 (Hospital No. 24404).—V. V., man, aged 50, married, with no children, admitted, May 14, 1917, had a superficial ulcer, 1.5 cm. in diameter, on the middle of the vermilion surface and adjacent portion of the skin surface of the upper lip. No enlarged cervical lymphatics were palpable.

The lesion had first been noticed two and one half years before, and had slowly grown to its present size. The patient had been a heavy smoker. He had had no previous treatment.

May 14, 1917, 70 mc., in one 2 mm. lead plaque, 2 cm. square, were applied for four hours.

June 29, retrogression was almost complete.

July 23, 65 mc., in five 0.5 mm. silver tubes, set in dental compound, were applied for one and one-half hours.

October 5, there was no evidence of disease.

Feb. 15, 1918, there was no evidence of disease.

Case 4 (Hospital No. 24422).—P. R., man, aged 44, laborer, married, with children, admitted, May 21, 1917, had an ulcer 2 cm. long and 1.25 cm. wide, in the middle of the vermilion surface of the lower lip. There was slight submucous infiltration. The base and edges were characteristically indurated. The pathologic diagnosis was epidermoid carcinoma.

The lesion had first been noticed as a small nodule, two months before. The patient had been a moderate smoker, and drank only beer in moderation. The teeth had no sharp, decayed edges, although they showed the usual signs of neglect in the laboring class. Syphilis was denied, and the Wassermann reaction was negative.

Treatment:

May 21, 1917, 315 mc., in seven rubber-covered 1 mm. platinum tubes, were applied for one hour. The patient failed to return as requested for a completion of this treatment, which was incomplete, and when next seen, July 20, the old lesion had advanced, forming an ulcer 3.5 cm. long by 1.75 cm. wide, with an infiltration of the substance of the lip to a depth of 0.5 cm. The ulcer had now caused a definite defect in the lip, and a hard lymph node, 2 cm. in diameter, was palpable in the left submaxillary space.

July 24, 156 mc., in twelve 0.5 mm. silver tubes, were applied over an area of 12 sq.cm., in dental compound, for three hours.

August 4, the enlarged node in the left submaxillary space was removed, and found on microscopic examination to contain epithelioma.

September 24, the left half of the lesion had completely retrogressed; at the right extremity an indurated nodule, 1.5 cm. in diameter, was still present; 525 mc., in seven 0.5 mm. silver tubes, were applied over an area of 6 sq.cm., to the right extremity of the lesion.

October 12, a considerable retrogression had occurred in the area treated. Two enlarged lymph nodes had appeared in the submental space.

November 5, 360 mc., in six 1 mm. platinum tubes, embedded over an area 6 sq.cm., to a depth of 5 mm., in a mold of dental compound, were applied for five hours.

November 19, under local anesthesia, the submental glands were removed. Microscopic examination revealed that they were invaded by carcinoma.

Jan. 30, 1918, new enlarged lymphatics were discovered in the right submaxillary region, and the left parotid and deep cervical regions. Complete dissection of both sides of neck, with removal of all glands was performed. Retrogression in the lip was practically complete.

Case 5 (Hospital No. 24456).—J. F., man, aged 65, married, with seven children, admitted, May 31, 1917, had an ulcer, 2.5 cm. in diameter, with hard, thick base and edges, on the right extremity of the vermilion surface of the lower lip, and involving the angle of the mouth and a small portion of the adjacent portion of the upper lip. No enlarged lymphatic glands were palpable in the neck.

Two years before the present lesion had first been noticed as a thickening of the right extremity of the lower lip. It later ulcerated and increased in size. Nine months before it was excised at Bellevue Hospital. It recurred in two months' time. The patient had smoked a corn-cob pipe all his life, used alcohol in moderation, and denied syphilis and any direct trauma to the lip. The teeth did not appear to have been a causative factor.

June 5, 1917, 336 mc., in fourteen 1 mm. platinum tubes, embedded in a mold of dental composition, were applied for five hours.

September 20, there was no evidence of disease present.

Jan. 17, 1918, there was no evidence of disease.

Case 6 (Hospital No. 24492).—S. E., man, aged 58, married, with three children, a chauffeur, admitted, June 13, 1917, had an ulcer, 2 cm. in diameter, on the mucocutaneous juncture of the right side of the lower lip. It was slightly elevated, with irregular, nodular, indurated base and edges. There were no enlarged cervical lymphatics in the neck.

Thirteen months before, the lip had been injured at the site of the lesion during the extraction of a tooth. The ulcer so caused never healed, but gradually developed into the present lesion. One month ago an unsuccessful attempt was made to cure the ulcer by an electric needle. The patient smoked a pipe and cigars, and used alcohol in moderation. Syphilis was not demonstrated.

June 13, 1917, 210 mc., in six 0.5 mm. silver tubes, embedded to a depth of 1 mm. in a mold of dental compound, was applied for four hours.

July 27, there was no evidence of disease.

Feb. 11, 1918, there was no evidence of disease.

Case 7 (Hospital No. 24505).—C. S., man, aged 70, married, with children, a physician, admitted, June 15, 1917, had an ulcer with characteristically indurated base and edges, on the left half of the vermilion surface of the lower lip, near the middle line. The ulcer measured 1.5 cm. in diameter, and there was definite infiltration of the substance of the lip beneath the mucosa.

The patient had first noticed the lesion as a small sore on the lower lip two years before. It had resisted all treatment, which had consisted of various local medicinal applications and fulguration. The patient was an incessant smoker, did not use alcohol, and gave no history of direct trauma or injury from the teeth. He denied syphilis.

June 15, 1917, 106 mc., in seven 0.5 mm. silver tubes, embedded 1 mm. within a mold of dental composition, were applied for two hours.

October 5, absolutely no evidence of disease was present.

December 19, there was a small indurated patch, 2 mm. in diameter, on the right end of the site of the old lesion. The patient since last being seen had continued to smoke incessantly. On this day, 250 mc., in four 0.5 mm. silver tubes, embedded 1 mm. deep in a mold of dental composition, were applied over an area of 3 sq.cm. for three-quarter hour.

Feb. 15, 1918, the reaction from the last treatment had completely disappeared. There still remained a minute thickening at the site of the patch last treated.

Case 8 (Hospital No. 24566).—H. T., man, aged 72, married, admitted, July 3, 1917, had an indurated ulcer, 0.5 cm. in diameter, on the middle of the vermilion surface of the lower lip. Between this ulcer and the left angle of the mouth was a second ulcer, 1 cm. in diameter. Its base was indurated, and surrounding it there was a definite, though small, submucous infiltration of the substance of the lip. At the left angle of the mouth there was a still larger ulcer with an indurated base and a surrounding submucous infiltration to a depth of 0.5 cm.

The lesion had first been noticed six months before. It had been treated by a course of caustic application, applied twice a week for a period. The patient had been in the habit of smoking six cigars a day, holding them on the left side of the mouth. He denied syphilis, was not addicted to alcohol, and his teeth were in fair condition.

July 3, 1917, 150 mc., in ten tubes of 0.5 mm. silver, over 4 sq.cm. of dental compound, were applied for two hours.

October 22, all ulceration was healed, and retrogression appeared to be practically complete.

December 28, no evidence of disease was present.

Case 9 (Hospital No. 24567).—J. H., man, aged 55, married, admitted July 3, 1917, had an ulcerated neoplasm on the vermilion surface of the lower lip, midway between the angle of the mouth and the middle of the lip. The base and borders were indurated, and there was a submucous infiltration of about 0.5 cm. The whole lesion measured about 1.75 cm. in both directions. The lesion was diagnosed as epithelioma.

The lesion had first been noticed as a small ulcer, resembling a coldsore, sixteen months before. It was treated with caustic application several times, and carbon dioxid snow three times. It had progressively increased to the present size. Most of the patient's teeth had been removed, and those that remained were in poor condition. He denied syphilis, and had been a heavy smoker, usually using a pipe, which he had held in the left side of the mouth. Two years before, the urine was said to contain sugar, for which condition he received treatment for a short time.

July 3, 1917, 60 mc., in four 0.5 mm. silver tubes, were applied over an area of 3 sq.cm., embedded in dental composition, for two hours.

September 21, there was no evidence of disease.

December 28, there was no evidence of disease.

Case 10 (Hospital No. 24620).—D. D., man, aged 44, admitted, July 20, 1917, had had the right third of both the upper and the lower lips and the right angle of the mouth destroyed by an ulcer, the base and edges of which were hard and covered with a smooth, sloughing surface, which was noticeably free from the nodular character usually present in epithelioma. No enlarged glands were palpable in the submaxillary space. The adjacent portion of the lower lip was much thickened, but soft. The whole lesion measured 6 cm. long and involved the cheek as far back as the second molar tooth. The pathologic report was epithelioma associated with much granulation tissue. A search for spirochetes revealed none.

A small sore developed in the right side of the lower lip nine months before. It had progressively increased to the present size. In 1908 the patient believed that he had contracted syphilis in Cuba. He was treated with mercury and iodids, and had received twelve injections of arsphenamin (salvarsan) during the last six months. Three years before, a gastro-enterostomy had been made for ulcer of the stomach, supposed to be syphilitic in origin. Since last March he had been treated at Raybrook, N. Y., for pulmonary tuberculosis. His father and mother both died from cancer. The Wassermann reaction was at present negative.

Aug. 14, 1917, 360 mc., in thirty 0.5 mm. silver tubes in dental compound, were applied over an area 50 sq.cm. for three hours.

September 21, no real improvement was noted. The inflammation in the lesion had increased.

October 8, under local anesthesia, all apparently involved tissue was removed by the cautery. This attempt was unsuccessful; a recurrence took place in the floor of the mouth and in the submaxillary lymph nodes of the opposite side. The latter were dissected out under local anesthesia, November 14, and the procedure greatly relieved the pain.

December 18, the patient died.

Necropsy revealed cancer of the floor of the mouth on the edges of the cauterized region, which were hard and covered with necrotic tissue. The tissues in the left submaxillary space were necrotic and devoid of induration. There was advanced pulmonary phthisis of the right lung, and miliary tuberculosis of the upper lobe of the left lung. No cancer was noted elsewhere in the body.

Case 11 (Hospital No. 24775).—O. H., man, aged 38, married, with two children, soldier, admitted, Sept. 19, 1917, had an ulcer 2.5 by 1.25 cm. in diameter, in the middle of the vermilion border of the lower lip. It was covered with a scab, beneath which was an elevated papillary and indurated base.

The lesion had first been noticed four months before, when it resembled a coldsore on the lower lip. It became covered with a scab, and gradually increased to the present size. It had been frozen once with carbon dioxid snow, which caused a temporary disappearance of the lesion. The patient denied syphilis, gave no history of direct trauma, and did not indulge to any extent in alcohol. His teeth were in good condition, and he smoked only in moderation.

Sept. 19, 1917, 203 mc. in seven 0.5 mm. silver tubes, were applied over an area of 7 sq.cm. in dental compound for two hours.

October 29, retrogression was complete.

November 27, the lesion was entirely healed, with the exception of a minute radium ulcer on the lingual surface of the lip.

Case 12 (Hospital No. 24823).—J. McF., man, aged 49, married, admitted, Oct. 5, 1917. On the middle of the vermilion surface of the lower lip was a flattened ulcer, 1.5 by 1 cm., with an indurated base, which formed with the submucous infiltration and thickened edges a button-like mass, at least 1 cm. thick. A short distance to the right of this ulcer was another ulcer, 5 mm. in diameter; and about 0.5 cm. to the left was a third ulcer, 0.75 cm. in diameter. Both these lateral ulcers were devoid of deep infiltration.

One year before, an ulcer had appeared in the middle of the vermilion surface of the lower lip. Five months before, another ulcer appeared on the left; and three months before, a third appeared on the right of the first lesion. No previous treatment had been given. The patient had smoked moderately, and gave no history of trauma or injury from the teeth. Eight years before, he was supposed to have had active pulmonary tuberculosis; and thirty years before, he had a chancre, followed by treatment for only one month.

Oct. 6, 1917, 162 mc., in nine 0.5 mm. silver tubes, embedded over an area of 4.5 sq.cm., 5 mm. deep in dental compound, were applied for two hours.

Jan. 21, 1918, no evidence of disease was present.

Case 13 (Hospital No. 24843).—G. S., man, aged 61, married, admitted, Oct. 12, 1917, had an ulcer, 2 cm. long, in the middle of the vermilion surface of the lower lip. Its edges and base were hard and nodular, and there was definite infiltration of the substance of the lip beneath the base and under the margins. A small pea-sized nodule of uncertain significance was palpable in each submaxillary space.

Two years before, a small ulcer had developed in the center of the lower lip. It remained fairly stationary till two months before, and since then had steadily increased in size. The patient had always smoked excessively. There had been no other trauma, and he denied syphilis.

Oct. 12, 1917, 420 mc., embedded over an area 10 sq.cm., in 0.5 mm. silver tubes, 5 mm. deep in dental composition, were applied for one and one-half hours. Following this treatment a very satisfactory retrogression resulted; December 27, however, enough thickening remained to indicate another treatment.

December 27, 133 mc., in seven 1 mm. platinum tubes, distributed over an area of 7 sq.cm., at distance of 0.5 cm., were applied for five and one-third hours.

Feb. 11, 1918, retrogression was almost complete.

Case 14 (Hospital No. 24910).—A. F., man, aged 58, married, admitted, Nov. 2, 1917, had an ulcer, 1.25 cm. in diameter, just to the right of the middle line on the vermilion surface of the lower lip. The surrounding tissues of the lip were infiltrated to a depth of 1 cm., both around the margins and beneath the lesion.

Seven years before, a small ulcer had appeared at the site of the present lesion. It scabbed over from time to time, and increased in size. Two years before, the patient had received a series of roentgen-ray treatments, during a period of six months. These apparently healed the lesion, but about seven months before it had again ulcerated, and steadily increased in size in spite of a continuation of the roentgen-ray treatment. The patient formerly had been a heavy smoker. There was no other history of trauma or injury from the teeth. He denied syphilis.

Nov. 2, 1917, 115 mc., in three 0.5 mm. silver tubes, embedded 5 mm. deep in dental compound, were applied for one and one-half hours. A temporary improvement, noted November 16, was followed by a marked increase in the size of the lesion, noted November 30.

December 3, 832 mc., in seven 1 mm. platinum tubes, were applied over an area of 10 sq.cm., from 0.5 to 1 cm. deep in dental compound, for one and one-fourth hours. Retrogression proceeded satisfactorily until Feb. 13, 1918, when a slight increase in the thickening of the lip had developed.

Feb. 13, 1918, 202 mc., in 1 mm. platinum tubes, over an area of 28 sq.cm., 5 mm. distant, were applied for twelve hours.

Case 15 (Hospital No. 24987).—S. D., woman, aged 84, a widow, who had had fifteen children, admitted, Nov. 30, 1917, had an elevated, nodular ulcer, 2.25 by 1.5 cm., on the vermilion surface of the left half of the lower lip, but extending to a greater distance below on the skin surface. The edges and base were indurated, but the lesion was superficial, with practically no deep infiltration of the submucous tissues. There were no enlarged cervical lymphatics.

Twelve years before, the patient had first noticed a small pimple on the left half of the lower lip. This was irritated from time to time by scratching. It ulcerated and gradually developed into the present lesion. There was no history indicating syphilis or direct trauma or chronic irritation from tobacco. The patient had been edentulous for many years.

Nov. 30, 1917, 109 mc., in five mm. silver tubes, were applied over an area of 5 sq.cm., embedded 1 mm. deep in dental compound, for three hours.

Jan. 29, 1918, no evidence of disease was present.

Case 16 (Hospital No. 24994).—H. B., man, aged 72, married, admitted, Nov. 30, 1917, had an indurated ulcer surrounding the left angle of the mouth, which had been contracted at this end by a previous operation. The ulcer involved 2 cm. of the vermilion surface and a small part of the adjacent portion of the upper lip. Beyond the angle of the mouth the whole thickness of the cheek was infiltrated for a distance of 1 cm., and beneath the portion of the ulcer on the upper and lower lip, to a depth of 0.5 cm.

Ulceration first developed on the lower lip, eight years before. It followed an injury to the lip, produced by a clam shell during eating. Two months later the ulcer was excised. Two years later glandular metastases were excised from the neck. The present local recurrence was first noticed from six to seven months before.

Dec. 10, 1917, 921 mc., in seven 1 mm. platinum tubes, covering an area of 15 sq.cm., in dental compound, at a distance of from 0.5 to 1 cm. from the lesion, were applied for one and one-half hours.

Feb. 15, 1918, retrogression was almost complete, only a slight thickening at the angle of the mouth remaining.

Case 17 (Hospital No. 25007).—J. K., man, aged 52, married, carpenter, admitted, Dec. 4, 1917, on the vermilion surface of the lower lip, a little to the right of the middle line, had a partly ulcerated, warty mass, 2.5 by 1 cm., formed by the apparent coalescence of three papillomatous growths. The lesion was superficial without apparent infiltration beneath the mucosa.

Three years before, a small "sore" developed on the right side of the lower lip. It would alternately crust over and bleed. In the last three months the lesion had increased rapidly in size.

Dec. 10, 1917, 266 mc., in seven 0.5 mm. silver tubes, distributed over an area of 9 sq.cm., at a depth of from 2 to 4 mm. in a mold of dental compound, were applied for three hours (88.5 per sq.cm.).

Jan. 4, 1918, no evidence of malignant tissue was present. There was a superficial, painless ulceration, caused by the radium, which was not entirely healed.

February 1, the lip had completely healed, and all induration was absent.

Case 18 (Hospital No. 25059).—J. H., man, aged 45, married, admitted, Dec. 21, 1917, had a superficial, indurated ulcer, 1.5 by 1 cm., on the vermilion surface of the right half of the lower lip. From near the center of the ulcer there arose a hard, hornlike scab, 0.5 cm. high. The teeth showed no jagged edges, and were in a fair state of preservation, though very dirty, and surrounded with advanced pyorrhea.

Two years before, the lesion had begun as a small ulcer, which had been excised fifteen months before. It had recurred in eight weeks, and had gradually grown to the present size. The patient smoked a pipe excessively, having formerly held it in the right side of the mouth. He denied syphilis, and drank moderately.

Dec. 21, 1917, 448.2 mc., in three tubes of 0.5 mm. silver, over an area of 2.5 sq.cm. in dental compound, were applied for half an hour.

Feb. 8, 1918, no evidence of disease was present.

COMMENT

The degree of success that we have obtained in the treatment of operable cancer of the lip by radium in the series of cases reported above, and the maintenance to date with such regularity of the healed condition in the earlier cases treated, justifies a continuation of the use of radium in operable cancer of the lip. It may be that the lapse of time will require some modification of this judgment. This method of treatment includes the careful observation of the patients after treatment for the possible development of metastatic lymph nodes, and the operative removal of such when they occur, with the implantation of radium in the wound. We believe that the treatment of cancer of the lip by radium will encourage earlier attention to this disease by the patient.

We recommend the application of radium emanation embedded in molds of the dental compound, and filtered through the thinnest material for the most superficial lesions. As a matter of convenience we have used 0.5 mm. of silver uniformly for all but the lesions with deep infiltration. While 0.5 mm. of silver has been unnecessarily heavy for the most superficial lesions, it has given uniformly satisfactory results in our cases. For the deeper lesions, however, nothing has surpassed the progressive, smooth and complete retrogression produced by filtration through 1 mm. of platinum. The tubes should be sunk 5 mm. in the dental compound, and for the ordinary lesion the dose should be 60 millicurie hours per square centimeter, when the filtration is through 0.5 mm. of silver, and 100 millicurie hours per square centimeter when through 1 mm. of platinum.

The use of emanation instead of radium element facilitates uniform distribution over the lesion. Provision for uniform distribution is the most important factor in obtaining a successful result. It is true that it is possible to approach the uniform distribution obtained by emanation with the radium element, provided this is put up in many minute tubes; but few users of radium element find it practical to divide their radium thus, and the attempt to treat these lesions by merely placing on them single tubes of radium element is inaccurate and often inadequate.

The superior adaptability of radium emanation for the treatment of cancer makes the use of the element itself obsolete, and for the vast majority of cancers it is inefficient.

375 Park Avenue.

ENTRANCE CONDITIONS IN MEDICAL SCHOOLS *

HARLEY E. FRENCH, M.D.
Dean, University of North Dakota School of Medicine
UNIVERSITY, N. D.

This brief paper can claim no merit as being entertaining; unfortunately it is unable to present a great deal of definite data; it is intended to present a point of view, and to elicit discussion and the necessary data from which to draw a conclusion.

Permit me to say in starting that I am in entire sympathy with the new ideal standard for medical entrance advocated by the Council on Medical Education of the American Medical Association — the two year college standard with certain required courses. Since its inception in 1905, the University of North Dakota School of Medicine has had requirements for admission somewhat higher than high school graduation. For ten years, or since 1907, it has been on the two year premedical college basis, with a course laid out for premedical students essentially the same as that outlined by the Special Committee of the Council on Medical Education, the Association of American Medical Colleges and the Association of American Universities. The chief difference between our curriculum and that of the committee is that we have always required a little more of modern foreign language and of some of the premedical sciences, and allowed less opportunity for election. While we have liked our own standard, I prefer for the general requirement the slightly more flexible outline suggested by the Special Committee, with which you are all familiar. I agree entirely that anything less than this standard of admission fails to give the student the necessary foundation; but while I am glad to see some medical colleges requiring a higher standard, and while I advise certain students every year to complete a four year college course before they begin the study of medicine, I should not like to see a higher standard than two years of college work become general.

The subject of this discussion is the discontinuing of the possibility of entrance conditions after Jan. 1, 1918. Last year you will remember that this Association voted to permit certain conditions until the beginning of 1918. The Council on Medical Education has heretofore also recognized the necessity for certain conditions, but always, perhaps, with the indication that the time would soon come when they would no longer be desirable; in its report, as published in The Journal, Aug. 18, 1917, page 547, published also as a reprint, and in the revised pamphlet, "Making the Right Start," the Council outlines the conditions that were permissible last fall, and indicates that first year medical students after Jan. 1, 1918, must be admitted only without conditions. Several medical schools have already announced a policy of admitting only those who satisfy all entrance requirements in every particular. Is it desirable to allow no entrance conditions?

In favor of the policy of no entrance conditions it may be urged that:

1. The student needs every bit of the required college work to enable him to pursue his medical studies satisfactorily.
2. Like the higher entrance requirements, it is demanded by the best interests of society.
3. If any entrance conditions are permitted at all, there would be a tendency on the part of both administrative officers and students to abuse the privilege; or schools cannot be trusted to administer conditions.
4. It would be simpler; making simpler bookkeeping, reports and records, obviating no little call for the exercise of judgment on the part of enrolling officers, and obviating possible conflicts in the student's program.

In favor of recognizing the necessity for continuing the well guarded entrance condition, I would urge that:

1. Well prepared and promising students who are slightly deficient in the requirements do present themselves for medical entrance.
2. The laws of many states and the requirements of state boards and medical schools demanding that the student attend four annual sessions of a recognized medical school will operate harshly on many good students unless some provision can be made for entrance conditions.
3. There is no sound pedagogic reason why a student of suitable age and general satisfactory preparation cannot carry part, not all, of the first year of the medical curriculum at the same time that he is finishing a small part of the required premedical work; many medical schools are now so related to a college of liberal arts that such a mixed enrolment is possible. Or if the medical school does not enjoy the relation to the college of liberal arts that makes such an enrolment possible, there is no sound reason why the selected student may not carry the first year of medicine with a condition in a small part of the required premedical work, and be permitted to remove the condition in the following summer.
4. Well conducted summer terms or quarters in many parts of the country make it possible for the student to make his standing regular by permitting him to take either the part of the first year of medical work that he failed to carry in the one instance above, or the required premedical work that has been postponed in the other.
5. There have been so many improvements in the ideals and standards of medical education, that a school that is worthy of continued existence might well be trusted to administer entrance conditions.

When I suggest this subject for discussion or for a possible paper, I had thought that should I be asked to prepare the paper, I should send out a questionnaire to ascertain the opinions of the deans of other medical schools, and attempt to get definite figures as to the number of students that would probably be involved. When the call for the paper came, however, the time seemed so short that I decided to omit the questionnaire, and to depend on the discussion at this time to supply more complete data.

REASONS FOR THE ENTRANCE CONDITIONS

To discuss briefly from my own experience the reasons that I have given for continuing the entrance condition, and incidentally to outline the way I have been accustomed to handle certain cases in the past, I might continue as follows:

1. There are many strong and promising students who present themselves with more or less irregularity

---

* Read at the Annual Congress on Medical Education and Licensure, Chicago, Feb. 5, 1918.

in their entrance credits. In the fall of 1917, I reported to the Council on Medical Education as first year medical matriculants eighteen students. Ten of these had survived our own premedical course in the University of North Dakota or had graduated in our own College of Liberal Arts with our medical requirements ever before them. These students were perfectly regular in every way, with total college credits varying from 64½ semester hours to 125 semester hours and the bachelor's degree; all of the ten presented all of the required work in English, modern foreign language, and the premedical sciences. The eight others were enrolled with conditions. One had the bachelor's degree and a year of graduate work from a neighboring state university, he was all right in English and the sciences, and could be given some advanced subject credit; but he lacked part of the second year of foreign language. A second had the bachelor's degree from a standard college, and had all of the required subjects excepting a year of physics. A third had 134 semester hours of college work, more than enough to receive the bachelor's degree, but he had failed to satisfy the language requirements of our College of Liberal Arts; he was all right for medical entrance except for one semester of German. A fourth presented college credits that would have admitted him to the senior year of the College of Liberal Arts, but, for unconditioned medical entrance, he lacked a second year of French. A fifth presented 70⅞ semester hours with all required work except four semester hours in biology. So far, I am sure all would agree that the cases are worthy, and that in every case conditioned entrance was permissible last fall. The remaining cases are nominally not quite so good. Without stopping to analyze them, I shall simply say that they represent promising students with by far the greater part of all of the required work accomplished who were given mixed arts medical enrolments, as I shall explain a moment later, and attention was called to their status in the report.

Whether we count it five out of fifteen or eight out of eighteen, the point is that under the rules of last fall our proportion of conditional entrances was large. Similar analyses, all based on our own two year college requirements, could be given for 1916, when four out of seventeen were lacking in a small part of the required work, and for every year the school has been in existence. I should suppose that 33⅓ per cent. would represent our average of the conditioned matriculations in the past.

What the situation is in other schools I cannot say. A recent letter from the dean of a large state university medical school shows that had the two year entrance requirement with no conditions been enforced in his institution last fall, only forty-one instead of 165 students could have been admitted, or that 75 per cent. of the present first year class in that medical school either have conditions, or would have them if the entrance requirement were two years of college work as outlined by the Special Committee.

2. With state laws, regulations of state boards, and requirements of probably all complete medical schools all calling for four years of residence and work in a lawfully established and reputable medical college, to say nothing of the fifth or intern year, I consider it an undesirable and an unnecessarily difficult handicap to place on a large proportion of promising students to deny them admission until they can enter without a condition. If there were no legal demands regarding time there would, of course, be no occasion for this discussion. It is not a sufficient answer to say that the student should have acquainted himself with medical entrance requirements and been prepared. Much of the literature of the Council on Medical Education, and the prominence given to premedical curriculums in many colleges and universities, are helping to make the situation better, and will continue to do so. In spite of all of this, however, many a good student does not come into contact with the literature and the announcements so familiar to us; many a student for one reason or another begins his college work and perhaps graduates in a college that still stresses the humanities, and in which it is difficult to secure all of the desirable courses for medical entrance no matter how alert the student may be; many a student in his early years of college work has not yet decided on his vocation, nor do I consider it either necessary or wise to expect every boy as he leaves high school and enters college to have made up his mind as to what his life work shall be; many good students change their minds even after receiving the bachelor's degree. If such a student lacks a great deal of the required work for medical entrance, he must, of course, spend a year or more in preparation; he should by all means have had the first year of chemistry and of modern foreign language and the greater part of the total requirements; but why should a student who is in general well prepared be denied admission, or required to wait a year, when a condition of from four to eight semester hours of college work in physics, biology, second year chemistry, or second year modern foreign language would enable him to begin his medical studies?

3 and 4. There is no valid pedagogic reason why certain conditions should not be permitted, and summer terms or quarters offer the student the opportunity to make his course regular. While I believe thoroughly in a proper sequence of courses, both in the arts and in the medical curriculum, and while I recognize the value of all the required premedical work as a foundation for the study of medicine, I see no reason why a strong student cannot handle gross anatomy at the same time he is studying physics or organic chemistry, or physiology while he is taking his second year of French or German; nor would the situation be materially different should he carry the first year of the medical curriculum regularly, and leave a required premedical subject in which he is deficient to be made up before the second year.

METHOD OF ENROLMENT

Since our school of medicine is closely related to the College of Liberal Arts, it has almost invariably been my practice in enrolling a so-called conditioned student to put on his card first of all the subject or subjects in which he is deficient, and then to fill out his enrolment with such part of the first year's medical curriculum as his time and schedule will permit. I enroll him, for example, in physics and gross anatomy and embryology, requiring him to omit the histology; or in second year French or German or in biology and in embryology and histology, and require him to omit the gross anatomy. I do not overload him or permit him to handle the whole first year of medicine with a premedical subject on the side, though some students might well handle such an enrolment. Sometimes, but rarely, I have enrolled such a student in the regular first year's medical curriculum and allowed him to postpone a small condition, for example, four hours of chemistry or language until the following summer. A medical school not enjoying the close relation to the College of Liberal Arts that we do would have to handle conditions in the latter way, if at all. We do not generally do so for several reasons: 1. It is better to make up all foundational and required work as early as possible. 2. Our summer term is short, and one cannot well make up a condition amounting to eight semester hours. 3. The student is sometimes unable, or at any rate fails, to make his course regular by the beginning of the second year, and so presents obvious difficulties at that time.

The student is expected to remove the irregularity, rarely a premedical requirement with us, usually a part of the first year's medical curriculum, by work in a summer term or quarter, and in our case this usually means that he goes to some larger neighboring medical school for the summer, since the demand is not sufficient to justify us in offering summer courses in medicine. If the student does this, his work becomes regular for the second year, and if at the close of this year he satisfies all requirements, he is given the bachelor's degree in the combination course, and is certified to clinical schools as having completed two years of medicine. If he fails to make his course regular, and returns to us for the second year, he is enrolled in what he has failed to carry of the first year's curriculum, and so much of the second year's work, as his time and schedule, and the prerequisites of the courses of this year, will permit. In this case he cannot receive the degree in the combination course, and he is certified as having done only such part of the medical curriculum as he has actually completed; if he receives a degree at all it is because he satisfies the requirements of the College of Liberal Arts, and this he may or may not do. A summer quarter's work may now make him eligible for junior standing in a clinical school. The student that does not make his course regular must of necessity take more time.

SCHOLARSHIP OF CONDITIONED MEN

Our experience with conditioned students bears out the contention that they should be given an opportunity, and that they can do the work satisfactorily. In my present freshman class in gross anatomy, the strongest two students are men with conditions. In our present sophomore class the strongest man is one who has been regular from the start, but in the classes graduating in the combination arts-medical course in both 1917 and 1916, the strongest students and the winners of Phi Beta Kappa and of a prize for scholarship given by the local medical society were men who entered with conditions, and who made their work regular by attending summer terms or quarters in other schools between the first and second medical years. Going back to 1915, the strongest man had been regular from the start; but it might be noted in passing that in his first year at the university, or as an arts freshman, he did not enroll in the premedical curriculum, and that it took work in two summer terms to make his medical entrance regular, as it was, at the beginning of his third year; this fact simply illustrates that the course, or curriculum, leading to medical entrance in the briefest time is pretty straight and narrow.

I have looked over our list of students for the last five years carefully, and it is my judgment that while the honors are fairly even, the advantage figured from any point of view is slightly, but clearly, in favor of those that have entered with conditions. I should not argue from this that to have an entrance condition is a good thing in itself: I should explain the fact by saying that as a class our conditioned students have been a little older and more experienced, a little better prepared in general, though lacking in some particular, and also a little more carefully selected. An enrolling officer must use judgment in any case. We think, for example, that quality in work is quite as essential as quantity in either case, and in our catalogue we announce a plan in our effort to secure quality.

CONSISTENCY OF THE POLICY

I have discussed our way of handling conditions in the past when they were permissible by the rules of this Association and of the Council to attempt to show that they can be handled without violating the principles of pedagogy. Two years of college work and all of the specified English, modern foreign language, and premedical science are undoubtedly necessary to enable the student to pursue medicine successfully; but I see no inconsistency between this principle and a policy that would allow a promising student with 70 semester hours of college work, for example, but who is short 4 semester hours of biology, to begin his status as a medical student, and to handle a condition as I have indicated. College physics I consider absolutely necessary for both the study and the practice of medicine; but the only early medical subject for which I should suppose it ought to be considered a pedagogic prerequisite is physiology, which is usually begun in the second semester of the first year, if not in the second year; it cannot well be urged, then, that a condition might not at times be permitted in physics. Without discussing any of the other subjects in a similar way, permit me to say that it seems to me that it cannot be urged that the best interests of society demand a policy of no conditions. Society is, indeed, vitally interested in the thorough preparation of medical men; it has been a realization of the needs of society that has brought about the desirable changes in medical education; but the plan I have in mind takes nothing from the student's preparation, and allows no substitutions; only when the student satisfies all requirements is he finally passed or approved.

Whether schools can be trusted longer to administer such a policy, or whether the administrative difficulties, both for the schools and the officers of central bureaus such as that of the Council, are insuperable, I cannot say. Surely the great objection to a policy of continuing the possibility of the entrance condition must lie here. The matter seems to me so important, however, that I hope it will be given careful consideration.

I am sure I shall not be misunderstood as pleading for lower standards, or for the weak student who through failure in one or more subjects in his premedical course is unable to satisfy medical entrance in the briefest possible time. In the past, when conditions were permissible by the rules of this Association and of the Council, the University of North Dakota has attempted fairly to extend its usefulness as I have indicated. It has seemed to me that a school of medicine favorably located should do this. Should the Special Committee or any similar body representing the best judgment in medical education not see fit to reestablish the policy, we shall cheerfully acquiesce.

As indicated earlier in the paper, I have been unable to present definite data from the experience of other schools. It is to be hoped that the discussion will bring out these data. The questions are: Is the group of students who are on the whole well prepared but who lack in some particular sufficiently large to merit consideration? Is it fair to them, or necessary in the effort to secure and maintain proper standards, to deny them medical matriculation, or to require them to spend another year on premedical work before they are accepted? Are such students able to pursue the study of medicine successfully? Can provision be made that will at the same time be fair to them, fair to those who enter with all requirements satisfied, and operable without abuse?

HERPES ZOSTER AND CHICKENPOX

BENJAMIN GOLDBERG, M.D.
AND
FRANCIS D. FRANCIS, A.B., M.D.
Resident Physician and Attending Physician, Respectively,
Cook County Hospital
CHICAGO

During the month of January, 1918, at the Cook County Hospital, there were admitted three patients who had herpes zoster with a simultaneous chickenpox. This was of such unusual occurrence that the literature was consulted. Head,[1] in 1900, described a patient, a boy, who developed a herpes zoster on the fifth dorsal region which in twenty-four hours was followed by a typical chickenpox eruption. Corlett,[2] in 1905, cited four such occurrences, in adults aged, respectively, 40, 44, 48 and 70 years. Bokay,[3] in a period of time extending from 1891 to 1909, observed nine different cases of herpes zoster, of various locations, which in the members of the families exposed only to the herpes, after incubation periods of intervals varying from eight to twenty days, resulted in the production of fifteen cases of chickenpox in their respective families.

Richardson[4] reports that in a convalescent scarlet fever ward, one of the patients developed a profuse herpes zoster of lower dorsal and upper lumbar distribution. The patient was not isolated, but was nursed in the main ward. Exactly two weeks following, chickenpox broke out in the ward, three patients being affected, and all three had been in the hospital longer than three weeks, the time being thirty, thirty-two and forty days, respectively. All of these patients were isolated, and no more cases of cross infection resulted.

REPORT OF CASES

Case 1.—A. O., man, aged 53, single, cook, admitted, Jan. 19, 1918, complained of a rash on the body, and of itching. About one week before, the patient had noticed a skin eruption at the side of his chest. This was of a "raw beef" color, and "burned" or tingled. Numerous small blisters formed on it. About three days following the onset, he noticed a series of small pimples and blisters. They were not accompanied by any subjective symptoms, and appeared over the face and trunk. The patient had had typhoid at the age of 25. Chancre and gonorrhea were admitted. He was addicted to the use of alcohol.

On the skin in the area composing the segment in the eighth to the ninth left dorsal region, terminating at the midline anteriorly and posteriorly, was an irregular patchy area of erythema, surrounded by vesicles in groups, and crusts, in an apparent stage of recrudescence. Over the face and trunk there were discrete, vesicular, pustular and crusted lesions, in various stages; there was an occasional lesion on the legs and arms. The fauces, pharynx and palate also showed a discrete distribution of vesicles and papules. The teeth were carious, and the patient had pyorrhea alveolaris. There was bilateral potential inguinal hernia. Otherwise the examination was negative.

The blood count revealed: leukocytes, 9,400; erythrocytes, 5,200,000. The Wassermann test was negative. A culture in 1 per cent. glucose broth and on Petri plates was sterile after ninety-six hours. The spinal fluid pressure was not increased. There were 6 cells per cubic millimeter. The Ross-Jones test for globulin was negative. Culture in 1 per cent. glucose broth and on blood agar plates was sterile after ninety-six hours. The urine was negative.

Case 2.—A. G., man, aged 38, married, laborer in a biscuit factory, admitted, Jan. 31, 1918, complained of pain and swelling of the right forehead and eye, with blistering. The patient stated that six days before he had developed a severe pain in his right eye, which became swollen. Next day there was a "burning or itching" feeling in the right forehead. This continued. A crop of blisters appeared which had persisted since. Two days following the onset he noticed a small eruption of pimples on his body; no subjective symptoms preceded this. He had had gonorrhea one year before; otherwise the previous history was negative.

Over the right half of the forehead, well demarcated at the midline, extending back to the hairline and down over the eyebrow, laterally to the upper temporal region, was an area of diffuse erythema, surrounded by large, irregular blebs. The right eye showed chemosis of the lids, with a slight superficial injection of the conjunctiva. Over the body, especially the thorax and abdomen, there was a discrete sprinkling of macules, papules, vesicles and pustules, with occasional crusting, in different stages. Very few of these lesions were seen on the extremities, and none on the face. There were also found adenopathy, posterior cervical, epitrochlear and inguinal; marked pyorrhea alveolaris, and hypertrophied injected tonsils.

The blood count revealed: leukocytes, 10,200; erythrocytes, 4,800,000. The Wassermann test was negative. A culture in 1 per cent. glucose broth and on plates was sterile after ninety-six hours. The spinal fluid was clear. There were 4 cells per cubic millimeter. The Ross-Jones test for globulin was negative. A culture in 1 per cent. glucose broth and on blood agar plates was sterile after ninety-six hours. The urine was negative.

Case 3.—T. P., man, aged 27, single, sailor, admitted, Jan. 3, 1918, complained of pain and swelling of the right eye. About two weeks before he began to have a sharp pain over the right eyebrow. This pain was not very severe. Two days before, the eye became swollen so that the patient could not open it, and at the same time numerous blisters appeared on the forehead over it. Previous illnesses were denied.

Over the right side of the forehead, extending down to the lower eyelid, and laterally, and midline to a line on a level with the external canthus of the right eye, was a sharply defined elevated reddish area, slightly edematous, covered with vesicles and blebs. The eyelids were markedly chemotic, and could not be opened; a yellowish serum exuded between the lids. The neck, chest, abdomen and back showed a sprinkling of papules and vesicles, the vesicles being clear and having a red areola. Several of the teeth were carious, but otherwise were negative. The urine was negative.

COMMENT

Etiologically, von Bärensprung,[5] in 1863, first demonstrated herpes zoster as being an acute inflammatory condition of the ganglion corresponding to the region affected. Head and Campbell,[6] in 1900, pathologically demonstrated the presence of micro-organisms in the nerve radicles involved, and contended that herpes zoster was an acute specific disease. This was later experimentally proved by Rosenow and Oftedahl,[7] in their work on specific streptococci selection, by isolating streptococci from tonsils, pyorrheal abscesses, sputum and spinal fluid in man with herpes, and producing herpes, with corresponding ganglionic lesions, by animal inoculation with these strains of organisms.

As to chickenpox, nothing has ever been definitely determined etiologically. Tyzzer,[8] in a histopathologic study of chickenpox vesicles, found certain bodies enclosed in the nuclei and cytoplasm of the cells involved. These he considered typical of chickenpox, but he was unable to produce new lesions by their inoculation, and had to consider them as nonparasitic. Keysselitz and Mayer[9] believed that the inclusion bodies of chickenpox were analogous to cytoryctes and that they were not in themselves definitely parasites, but contained the infective virus.

Very little else has been discovered.

COLORIMETRIC DETERMINATION OF REACTION OF BACTERIOLOGIC MEDIUMS AND OTHER FLUIDS

GEORGE D. BARNETT, M.D.
Passed Assistant Surgeon, U. S. Naval Reserve Force
AND
HERBERT S. CHAPMAN, M.D.
Assistant Surgeon, U. S. Navy
SAN FRANCISCO

The colorimetric methods in common use for determining and adjusting the reaction of bacteriologic mediums and other fluids involve the use of standard solutions of known hydrogen ion concentration. A variety of such solutions has been described, and they are readily prepared by any one having a moderate chemical equipment and ability. Just now, however, many men with comparatively little chemical training are confronted with problems of this nature, and the method here described has therefore been devised to accomplish a fairly accurate determination of hydrogen ion concentration without the necessity of preparing standard solutions or of depending on those prepared by others. We are here concerned only with reactions lying between 7.0 and 8.0, and only phenolsulphonephthalein has been used as an indicator. Other indicators and other ranges of acidity will be investigated later.

In this method use is made of the principle of superimposing the two extreme colors of the indicator, as used by Clark and Lubs,[1] following Salm,[2] in determining the so-called half-transformation points of indicators. Within the range of its transition from red to yellow, we may regard the observed color of a phenolsulphonephthalein solution as composed of a definite amount of red plus a definite amount of yellow, and such a color may be exactly duplicated by superimposing the extreme red and the extreme yellow of the indicator in proper concentrations. Thus, if to one test tube we add 5 c.c. of dilute acid, and to another similar tube 5 c.c. of dilute alkali, and to each add 5 drops of phenolsulphonephthalein solution, a bright yellow will be produced in the first tube and a bright red in the other. But if we look toward the light through both tubes, a color will be observed that is half way between the yellow and the red. In fact, it will be identical with the color produced by 10 drops of the phenolsulphonephthalein solution in 5 c.c. of a standard solution having a p_H of 7.9. This is the half transformation point, and is a definite constant for this indicator. But if instead of using equal amounts of indicator in each of the two tubes we vary the partition of the 10 drops of indicator between them, then by superimposing each pair and viewing them by transmitted light, a series of colors will be produced which will cover the range of usefulness of the indicator; and once such a series is "calibrated" against solutions of known hydrogen ion concentration, it may be used as a standard series for the determination of unknown reactions.

Results obtained by such a procedure in the case of phenolsulphonephthalein, comparison being made with phosphate solutions prepared according to Sörensen,[3] are as shown in the accompanying table.

RESULTS WITH PHENOLSULPHONEPHTHALEIN

Acid Tubes Phenolsulphonephthalein Solution, Drops	Alkali Tubes Phenolsulphonephthalein Solution, Drops	p_H
9	1	6.9
8	2	7.2
7	3	7.5
6	4	7.7
5	5	7.9
4	6	8.1

OUTLINE OF METHOD

Apparatus and Chemicals Required.—1. Clean test tubes. These must be of approximately the same diameter. An equal volume of water is measured into a number of tubes, and fifteen or twenty are selected for use in which the water stands at about the same level.

2. A 5 c.c. pipet.

3. A medicine dropper drawn out to a fairly fine point.

4. A buret.

5. An indicator solution. A convenient solution (0.01 per cent.) of phenolsulphonephthalein is prepared by diluting 1 c.c. of the usual solution used for kidney function tests (1 c.c. = 6 mg.) to 60 c.c. with distilled water. No accuracy is necessary, provided the same solution is used throughout.

6. Roughly normal and twentieth normal sodium hydroxid.

7. Hydrochloric or sulphuric acid.

Preparation of Standard Color Series.—Twelve test tubes are placed in two rows of six. Into each tube of one row 5 c.c. of dilute alkali are placed. (The twentieth-normal sodium hydroxid may be used, or any solution sufficiently alkaline to bring out the maximum red color of the indicator.) Into each tube of the other row, 5 c.c. of very dilute acid are placed (One drop of concentrated hydrochloric or sulphuric acid to 100 c.c. of distilled water is sufficiently strong. Strong acid is to be avoided in the case of phenolsulphonephthalein, on account of its secondary color change.) Into the six acid tubes, 9, 8, 7, 6, 5 and 4 drops, respectively, of indicator are placed. Into the six corresponding alkali tubes, 1, 2, 3, 4, 5 and 6 drops of indicator are placed. If the dropper is held vertically, the drops will be practically of a size. Each pair of tubes thus contain 10 drops of indicator between them, and the series of six pairs, when viewed by transmitted light, will correspond to p_H values of 6.9, 7.2, 7.5, 7.7, 7.9 and 8.1 (as in the table) when compared with 5 c.c. volumes of any solution containing 10 drops of the same indicator solution. In order to determine the hydrogen ion concentration of an unknown solution whose reaction lies within this range, 5 c.c. of it are placed in a test tube, 10 drops of indicator are added, and its color is compared with those of the six pairs of tubes. The use of a second tube containing distilled water to form a pair with the unknown is to be recommended, but does not appear to affect the results appreciably. The color series prepared in this manner is as accurate as that yielded by standard phosphate or other solutions when used in a similar apparatus, and can be prepared anywhere in a few minutes without the use of graduated apparatus or accurate quantitative solutions of any kind. As noted by Clark and Lubs,[1] the use of pairs of test tubes is a device which is "optically very imperfect, but it works fairly well."

TITRATION OF MEDIUMS

One c.c. of the medium to be titrated is added to 4 c.c. of distilled water in a test tube. Ten drops of indicator are added, the color is compared with the color standards if it is desired to determine the initial reaction, and titration to the desired hydrogen ion concentration with twentieth-normal sodium hydroxid is performed. Fifty times the amount used will represent the amount of normal sodium hydroxid to be added to 1 liter of medium. If in carrying out the titration sufficient sodium hydroxid solution is added so that the indicator color is appreciably diluted, the end-point tubes of the comparator should be filled to a similar volume before the final comparison is made. If desired, in comparing colors, use may be made of the block described by Hurwitz, Meyer and Ostenberg,[4] though practically it has not been found to increase the accuracy appreciably. This is a wooden block in which two pairs of adjacent holes have been drilled to receive two pairs of test tubes. The holes are connected by slits so that each pair may be viewed by transmitted light. In this procedure one pair of holes would contain the acid-alkali pair chosen for an end-point, and the other the diluted mediums and a tube of distilled water. Compensation for colored fluids can usually be accomplished according to the principle introduced by Walpole,[5] by using in one row of the color standard series 5 c.c. amounts of the fluid made acid (or alkaline).

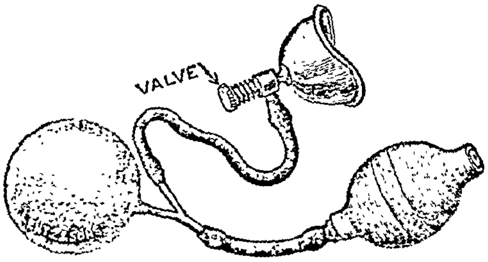
Clinical Notes, Suggestions, and New Instruments

ARTIFICIAL RESPIRATION IN ASPHYXIA NEONATORUM

Clarence L. Heald, M.D., Cedar Rapids, Iowa

Of the classic methods of artificial respiration in asphyxia neonatorum, mouth-to-mouth insufflation has proved more efficient than the methods dependent on manipulation of the child The manipulative methods of Prochownick (rhythmic compression of the child's chest in inverted suspension), rhythmic flexion and extension of the child's body, and Schultz' swingings are all useful in asphyxia livida, but in the more critical condition of asphyxia pallida, mouth-to-mouth insufflation or insufflation through a tracheal catheter will frequently succeed after these methods have failed.

There are, however, serious objections to mouth-to-mouth insufflation: 1. The delicate air vesicle may be ruptured. Bichat has proved the possibility of blowing air into the vessels near the heart if too much force is used. 2. There is danger of infection of the child by the operator. 3. The insufflated air has already been deprived of much of its oxygen, and is laden with carbon dioxid. 4. The air cannot be changed with sufficient rapidity to oxygenate the blood. 5. The method is laborious and cannot be kept up long by one person. 6. In asphyxia pallida this, as well as all the indirect methods of artificial respiration, is too often futile.



Instrument for artificial respiration in asphyxia neonatorum.

Some years ago I had an instrument made for artificial respiration in infants which has been very satisfactory in these cases. It consists of a syringe bulb connected by rubber tubing with an air valve in the dome of a small helmet-shaped mask, and by a Y tube with an ordinary rubber toy balloon. The latter serves as a reservoir, and, as its expansile tension is about 8 mm. of mercury, it prevents the air pressure in the child's lungs from rising above that point. It also produces a uniform, steady flow of air.

It is essential that the upper respiratory passages be clear before artificial respiration is started. In any case, therefore, in which it is probable that the placental circulation has been cut off before the head is born, as in breech presentation or prolapse of the cord, a tracheal catheter should be introduced and the trachea cleared by suction. After the mouth is cleared out with the gauze-covered finger, a thread on a needle is passed through the tongue to hold that organ well forward, but not outside of the mouth. A towel is wrapped snugly, but not tightly, about the child's abdomen to prevent air from entering the stomach. While an assistant keeps the balloon inflated by compressing the bulb, the operator holds the mask, with its long diameter transversely, over the child's mouth, including the chin, but not the nose. With the index finger of the same hand he manipulates the piston of the air valve, pressure on which allows the air to flow. With the finger and thumb of the other hand he alternately compresses and releases the nostrils through which expiration takes place. Pressing the air valve piston, at the same time compressing the nostrils to prevent escape of air, he inflates the lungs. Simultaneous release of the air valve piston (stopping the air flow) and release of the nostrils allow expiration to affected. Head and Campbell,[6] in 1900, pathologically demonstrated the presence of micro-organisms in the nerve radicles involved, and contended that herpes zoster was an acute specific disease. This was later experimentally proved by Rosenow and Oftedahl,[7] in their work on specific streptococci selection, by isolating streptococci from tonsils, pyorrheal abscesses, sputum and spinal fluid in man with herpes, and producing herpes, with corresponding ganglionic lesions, by animal inoculation with these strains of organisms.

As to chickenpox, nothing has ever been definitely determined etiologically. Tyzzer,[8] in a histopathologic study of chickenpox vesicles, found certain bodies enclosed in the nuclei and cytoplasm of the cells involved. These he considered typical of chickenpox, but he was unable to produce new lesions by their inoculation, and had to consider them as nonparasitic. Keysselitz and Mayer[9] believed that the inclusion bodies of chickenpox were analogous to cytoryctes and that they were not in themselves definitely parasites, but contained the infective virus.

Very little else has been discovered.

COLORIMETRIC DETERMINATION OF REACTION OF BACTERIOLOGIC MEDIUMS AND OTHER FLUIDS

GEORGE D. BARNETT, M.D.
Passed Assistant Surgeon, U. S. Naval Reserve Force
AND
HERBERT S. CHAPMAN, M.D.
Assistant Surgeon, U. S. Navy
SAN FRANCISCO

The colorimetric methods in common use for determining and adjusting the reaction of bacteriologic mediums and other fluids involve the use of standard solutions of known hydrogen ion concentration. A variety of such solutions has been described, and they are readily prepared by any one having a moderate chemical equipment and ability. Just now, however, many men with comparatively little chemical training are confronted with problems of this nature, and the method here described has therefore been devised to accomplish a fairly accurate determination of hydrogen ion concentration without the necessity of preparing standard solutions or of depending on those prepared by others. We are here concerned only with reactions lying between 7.0 and 8.0, and only phenolsulphonephthalein has been used as an indicator. Other indicators and other ranges of acidity will be investigated later.

In this method use is made of the principle of superimposing the two extreme colors of the indicator, as used by Clark and Lubs,[1] following Salm,[2] in determining the so-called half-transformation points of indicators. Within the range of its transition from red to yellow, we may regard the observed color of a phenolsulphonephthalein solution as composed of a definite amount of red plus a definite amount of yellow, and such a color may be exactly duplicated by superimposing the extreme red and the extreme yellow of the indicator in proper concentrations. Thus, if to one test tube we add 5 c.c. of dilute acid, and to another similar tube 5 c.c. of dilute alkali, and to each add 5 drops of phenolsulphonephthalein solution, a bright yellow will be produced in the first tube and a bright red in the other. But if we look toward the light through both tubes, a color will be observed that is half way between the yellow and the red. In fact, it will be identical with the color produced by 10 drops of the phenolsulphonephthalein solution in 5 c.c. of a standard solution having a p_H of 7.9. This is the half transformation point, and is a definite constant for this indicator. But if instead of using equal amounts of indicator in each of the two tubes we vary the partition of the 10 drops of indicator between them, then by superimposing each pair and viewing them by transmitted light, a series of colors will be produced which will cover the range of usefulness of the indicator; and once such a series is "calibrated" against solutions of known hydrogen ion concentration, it may be used as a standard series for the determination of unknown reactions.

Results obtained by such a procedure in the case of phenolsulphonephthalein, comparison being made with phosphate solutions prepared according to Sörensen,[3] are as shown in the accompanying table.

Some one has insisted that bilateral equality of nystagmus time is important, so we have analyzed our figures from that standpoint, measuring the variation between right and left in each individual. We find that the individual variation in the good fliers is 1.37 seconds, in the average fliers 1.81 seconds, and in the poor fliers 1.47 seconds. Certainly here we do not have even a semblance of correlation between flying ability and individual variation in nystagmus time.

If we take simply the gross average time for each of the three classes of fliers, we find 24.2 seconds for the good, 24.8 seconds for the poor, and 26 seconds for the average fliers, in which case we have a reversed correlation as regards good and poor fliers.

There seems to be an opinion prevalent among men examining candidates for aviation that variation above the normal is more desirable than variation below. In our group of cases, however, the variation of the good fliers below 26 seconds compared to the variation above in the same group is 4.62: 1, while in the case of the average and poor fliers, the ratios were 2.31: 1 and 2.02: 1, respectively.

The only case afforded by this group of 100 men in whom there was evidently a very marked abnormality of semicircular canal function was in W. L. L., No. 50. His nystagmus time was: right, 15; left, 13. He had reversed falling and was excessively nauseated. Nevertheless he has proved thus far to be a very acceptable flier, and in this classification has been put in the average class.

TABLE 4.—SUMMARY OF RESULTS

	Good Fliers (35 men)	Average Fliers (44 men)	Poor Fliers (21 men)
Average variation	4.63 seconds	5.72 seconds	6.04 seconds
Average nystagmus time	24.2 seconds	26 seconds	24.8 seconds
Individual variation between right and left	1.37 seconds	1.81 seconds	1.47 seconds
Ratio of "variation above" to "variation below"	1:4.62	1:2.31	1:2.02

The evidence, therefore, seems to point to an absence of correlation between equilibrium tests, as established in the Bárány chair, and actual flying ability.

Correlation of Laboratory and Clinical Observations.—In the third annual report of the Medical Research Committee for 1916-1917, it is noted that a special investigation committee has been appointed for the purpose of further combined study of "Shock and the Better Correlation of Laboratory and Clinical Observations," consisting of Prof. F. A. Bainbridge, Prof. W. M. Bayliss, F.R.S.; Prof. Walter B. Cannon, Dr. H. H. Dale, F.R.S. (secretary); Lieut.-Col. T. R. Elliott, F.R.S., R. A. M. C.; Capt. John Fraser, R. A. M. C.; Prof. C. S. Sherrington, F.R.S.; Prof. E. H. Starling, F.R.S. (chairman), and Col. Cuthbert Wallace, C. B. Professor Cannon is making arrangements for coordinating the work of this committee with that of a similar committee of American physiologists. The committee in its report also expresses its gratitude to the Rockefeller Institute for Medical Research, and to Dr. Simon Flexner, director of the institute, for services rendered, and especially mentions the assistance that Professor Richards, with the sanction of the University of Pennsylvania, is giving to research work in its pharmacologic department; the cooperation of Prof. Walter B. Cannon of Harvard University in inquiring into the physiology of surgical and toxic shock; the valuable service of Professor Tileston of Yale University, and other Americans in the work at Hampstead or Colchester on cases of military heart disorder, and the collaboration of American workers in France with the committee. The committee accepts gratefully these individual acts of friendly help for American workers as an earnest of the growing cooperation between this work for the advancement of medical knowledge in the two countries, on behalf of either of them, with the allied armies in Fra

THE PNEUMONIAS: STREPTOCOCCUS AND PNEUMOCOCCUS GROUPS

JAMES G. CUMMING, M.D. (Ann Arbor, Mich.)
Major, M. R. C., U. S. Army

CHARLES B. SPRUIT, M.D. (Boston)

AND

CHARLES LYNCH, M.D.
Colonel, M. C., U. S. Army; Department Surgeon

FORT SAM HOUSTON, SAN ANTONIO, TEXAS

A conference of medical officers from Fort Sam Houston and Camp Travis was held, Jan. 3, 1918, for the purpose of considering the pneumonia situation. Various points in the determination of the causative organism in pneumonia following measles were considered, methods of procedure were suggested, and the laboratory force was organized to take up the work. A preliminary report[1] was sent to the Surgeon-General of the U. S. Army, Feb. 7, 1918. We present a part of the original report, together with additional cases and comments.

METHODS OF PROCEDURE, AND POINTS TO BE CONSIDERED

1. The presence or absence of type pneumococci and hemolytic streptococci in all cases of measles should be determined by the taking of throat swabs of all patients immediately on their entering the hospital.
2. Carriers of either organism should be segregated and given special care—especially after-care.
3. Cultures for hemolytic streptococci should be made of all patients, now in the convalescent wards, who have had pneumonia following measles.
4. Blood cultures should be made in all pneumonia cases occurring as complications of measles.
5. Cultures in blood agar should be made of all pus specimens from serous cavities for identification of pneumococci and hemolytic streptococci.
6. At necropsy, cultures in blood agar should be made of lung specimens, pleural and pericardial pus and the heart's blood.
7. All organisms isolated should be identified.
8. The presence or absence of agglutinins for organisms isolated from *postmortem* specimens should be determined in patients convalescing from pneumonia following measles.
9. Determination by throat swabs should be made of the percentage of measles patients who are healthy carriers of pneumococci or hemolytic streptococci—Type III hemolysis.
   (*a*) What percentage of these develop pneumonia?
   (*b*) What percentage of these separate groups come to necropsy?
10. Are the types isolated at necropsy the same as those isolated from throat swabs?
11. The advisability should be considered of vaccinating, by the intravenous method, all measles patients or all who are found to be healthy carriers of specific organisms with the predominating or specific types that are isolated from postmortem specimens. This refers especially to vaccination with hemolytic streptococci.
12. The hemolytic streptococcus pneumonias should be given special consideration in determining whether or not these have been classified as Group Type IV pneumonias.
13. Is there a possibility of a double infection with the type epidemic pneumonia and the streptococcus pneumococcus pneumonia?
14. What percentage of bronchopneumonias are hemolytic streptococcus pneumonias?
15. Is hemolytic streptococcus pneumonia a terminal infection in type pneumonia?
16. All hemolytic streptococci isolated from throats, serous cavity exudates, blood and postmortem specimens should be identified by specific agglutinating.
17. The types or groupings of streptococci should be determined by serologic reactions.

This preliminary report is made for the purpose o setting forth our findings, so that others may ma similar investigations elsewhere.

PREVALENCE OF PNEUMOCOCCI AND HEMOLYTI STREPTOCOCCI IN THROAT SWABS OF MEASLES PATIENTS

In pursuance of the plan to determine the presence or absence of type pneumococci and hemolytic streptococci in all cases of measles on entrance of the patients to the hospital, and to determine the percentage of measles patients who are healthy carriers of pneumococci or hemolytic streptococci, 291 swab cultures were made. Of these, 187 showed Types I and II hemolysis. Among these patients, twenty-five, or 13 per cent., developed complications as follows: otitis media, 5; bronchopneumonia, 4; tonsillitis, 4; scarlet fever, 3; lobar pneumonia, 2; mumps, 2; arthritis, 1; sinusitis, 1; acute bronchitis, 1; erysipelas, 1; cellulitis, 1; abscess of gum, 1. Among these twenty-five patients there were twenty-six complications. During the bronchopneumonia complication in the four cases referred to in this group, Type III hemolytic streptococci were isolated.

TABLE 1.—THROAT SWABS FROM MEASLES PATIENTS ON ENTERING HOSPITAL, PERCENTAGE OF COMPLICATIONS FOLLOWING MEASLES *

	No.	Per Cent.	Complications No.	Complications Per Cent.
Total swabs	291	100	..	..
Types I and II hemolysis	187	64	25	13
Type III hemolysis	88	23	36	41
Types I and III hemolysis	16	12	15	94
Total type III	104	35	51	49

* Types I, II and III refer to types of hemolysis, and not to groups of streptococci.

Of the total swab cultures, 104 showed Type III hemolysis, and among these, fifty-one, or 49 per cent., developed complications. In this group these were: bronchopneumonia, 34; empyema, 9; tonsillitis, 6; arthritis, 2; acute bronchitis, 2; mumps, 1; lobar pneumonia, 1; cellulitis, 1; pleural effusion, 1. Among the fifty-one patients there were fifty-seven complications.

It may be assumed that some of these complications (scarlet fever and mumps [?]) were merely incidental to the measles infection.

If only the pneumonia cases are considered in these two groups of throat findings, it will be noted that among those patients from whom Types I and II were isolated, 3 per cent. developed pneumonia; while among those harboring the Type III hemolytic streptococcus, 33 per cent. developed pneumonia.

The complications here referred to, aside from the pneumonias, are now under investigation in order to determine the causative organism.

From 291 *throat* swabs from measles patients, 35 per cent. hemolytic streptococcus carriers were revealed, and 33 per cent. of these carriers developed streptococcus pneumonia.

---

[1] Cumming, J. G.: An Investigation to Determine the Causative Organism in Post-Measles Pneumonia Cases.

It has been established that among measles patients in this series of cases, 33 per cent. of the identified streptococcus carriers developed streptococcus pneumonia. Whether or not this percentage is applicable to measles cases among the civilian population is a question as yet not determined.

SWABS FROM AVERAGE THROATS

Seventy swabs from average throats showed only 6 per cent. hemolytic streptococci. This corresponds to the percentage obtained by Smillie in his investigation of hemolytic streptococci. How is the low percentage among these, as compared with the percentage among measles patients on entrance to the hospital, to be accounted for? Is it possible that the streptococcus in the throat prepares the way for measles virus infection, and that the latter infection, in turn, produces a condition that is favorable to streptococcus pneumonia (measles catarrh) and an extension of this infection to the pleural and pericardial cavities, blood stream, joints, etc.? Is this supposition applicable to scarlet fever and its complications?

* S means positive for Type III hemolytic streptococci.
† "Measles pneumonia" means measles followed by pneumonia.
‡ P means positive for pneumococci.
§ II means Type II hemolysis, organism not identified.

HOSPITAL PROCEDURE FOR THE SEGREGATION OF MEASLES PATIENTS

Carriers of either organism, the streptococcus or the pneumococcus, should be segregated and given special care, especially after-care. On the basis that 35 per cent. of measles patients are streptococcus carriers and that 33 per cent. of these will probably develop pneumonia complications, and that cross infection of those not carriers is an important consideration in prevention, the wards should be divided into three sections. The first of these may be designated the detention section where all incoming patients are held, until by throat swabs they are identified as carriers or as "clean" patients. This information is obtainable in eighteen hours. The carriers may then be removed to the second or carrier section, and the clean patients segregated in the third section. It is especially important that all patients in the detention section be protected by the sheet method of separation against droplet infection.

The value of the sheet method is shown in the results of having carriers of hemolytic streptococci cough four times directly at agar plates held at a distance of about 2 feet. One hundred and thirty plates were used in this experiment, and an average of fourteen colonies developed on each. In addition, thirty-two blood agar plates were exposed in the same manner, with the result that the average number of colonies was the same as in the preceding experiment, and 12 per cent. bore colonies of hemolytic streptococci.

BACTERIOLOGIC FINDINGS IN BLOOD CULTURES OF PATIENTS WITH PNEUMONIA FOLLOWING MEASLES

Of patients with pneumonia following measles, twenty-eight blood specimens in all were tested. Of these, twenty-four were negative, while four, or 17 per cent., were positive for hemolytic streptococci; whereas in the series of necropsies reported (Table 2), it will be noted that a much larger percentage (58) of the specimens were positive.

BACTERIOLOGIC FINDINGS IN ANTEMORTEM PLEURAL EXUDATES

Of the sixty-one examinations of pleural exudates from patients in the pneumonia wards, organisms were found in forty-eight specimens. Of forty-one lobar pneumonia specimens, 59 per cent. proved to be pure streptococcus type III hemolysis, and 41 per cent. pneumococcus. Of seven bronchopneumonia specimens, 86 per cent. were streptococci, and 14 per cent. pneumococci. By consolidating these two groups, we find that 63 per cent. were hemolytic streptococci and 37 per cent. pneumococci.

BACTERIOLOGIC FINDINGS AT NECROPSY

In the thirty-one necropsies considered in Table 2, streptococci—Type III hemolysis—were isolated from twenty-one lung specimens, twenty-two pleural exudates, fourteen pericardial exudates, and fifteen heart's blood specimens.

In twenty-six, or 84 per cent., of the specimens from the serous exudates or heart's bloods, the streptococcus was isolated from pure culture, and in three, or 9.7 per cent., of the specimens it was coexistent with the pneumococcus; furthermore, it was found in one or more of these specimens in twenty-nine, or 94 per cent., of the necropsies, lobar pneumonia cases included.

The streptococcus was isolated in each of the twenty-four bronchopneumonia cases. Of these twenty-four cases, eighteen, or 75 per cent., are known to have followed measles.

Of the seven lobar pneumonia postmortem specimens, in only two was the pneumococcus unaccompanied by the hemolytic streptococcus. In two other specimens of this group, only the streptococci were found, and in the remaining three there were both pneumococci and streptococci.

In the lung specimen of Case 13, the ratio of pneumococci to streptococci was 350:2; while in the heart's blood it was 3:200.

In only one necropsy on a patient that had had pneumonia following measles was a type epidemic pneumococcus found, and this was coexistent with the hemolytic streptococcus; while in the seven lobar pneumonia cases, hemolytic streptococci were found, either in pure culture or coexistent with pneumococci, in five, or 71 per cent., of the necropsies.

It would appear that the hemolytic streptococcus was the cause of death in twenty-nine, or 94 per cent., of the thirty-one cases, lobar pneumonia cases included; and since this organism was found in fairly pure cultures in all lung specimens as well as in pure cultures, in either serous exudates or the heart's blood or both, in cases of pneumonia following measles, it may be concluded that the hemolytic streptococcus is the causative organism in this complication following measles, moreover, that it was the immediate cause of death in a large percentage of so-called lobar pneumonia cases.

Assuming that universal vaccination against the predominant type, or types, of the hemolytic streptococcus will protect against infection, it follows that if this procedure is carried out, the case rate as well as the mortality of the pneumonias, both pneumococcus and streptococcus, should be reduced by a large percentage.

BACTERIOLOGIC FINDINGS IN SWAB AND SPUTUM SPECIMENS

In the wards for patients with pneumonia following measles, swab and sputum specimens from twenty-four patients were examined for the hemolytic streptococcus. Of the swabs, 76 per cent. were positive, as were also 87 per cent. of the sputum specimens. In 55 per cent. of the cases the swabs as well as the sputum specimens were positive; while either swab or sputum was positive in 100 per cent. of the cases. These findings show the importance of taking both swab and sputum specimens.

IDENTIFICATION AND CLASSIFICATION OF THE PNEUMONIAS

On account of the unquestioned prevalence of streptococcus pneumonia, both as a complication of measles and as coexistent with lobar pneumonia, it is apparent that a new differential procedure for type identification must be devised.

In none of the lobar pneumonia cases which at necropsy showed both pneumococci and streptococci had an antemortem diagnosis of type epidemic pneumococci other than Type IV been made.

Of twenty specimens of sputum from lobar pneumonia patients submitted to the pneumococcus division for type identification, four were of Type I; four were not identified because the sputum specimens were not satisfactory (streptococcus pneumonia sputum is not always of the coffee-ground character); and twelve were not of Types I or II. All these specimens were submitted to the division of streptococcus investigators, and of the twenty specimens, nine showed Type I or II hemolysis, and the remaining eleven the hemolytic streptococcus—Type III hemolysis.

It is apparent that there is considerable confusion in checking the results of the two divisions of workers, and this is doubtless due to the fact that the streptococcus has not heretofore been recognized as a factor in the pneumonias. In this series of specimens the streptococcus was found in 55 per cent. of the cases, and as the mortality from the infection is high in the so-called "lobar pneumonia" cases, the identification of this organism in the sputum is important in determining the proper therapeutic treatment.

Failures by the mouse method are due to the virulence of the streptococcus for this animal, and to the possibility of a coexistent infection of both pneumococcus and streptococcus. If a double infection exists, either the mouse will not die, because of the small proportion of pneumococci in the sputum, or if it does die, the death may be due either to one of the type pneumococci, or to the predominance of hemolytic streptococci. From this it will be seen that the hemolytic streptococcus is not recognized by the mouse method, and that this method does not rule out hemolytic streptococci and other infecting organisms, as was formerly believed.

Although the Avery method is applicable under favorable conditions to the type pneumococcus pneumonias, it does not include in its procedure the identification of streptococcus pneumonia; and owing to the mucous cloud which is not thrown down by centrifugation, precipitin formation is at times difficult to detect.

From these facts it is apparent that the methods heretofore employed are inadequate for the diagnosis of all the pneumonias, and that an additional procedure must be added which will include the identification of the hemolytic streptococcus.

Since the pneumonias are of two main groups—pneumococcus and streptococcus—and as they may be coexistent, the isolation of the causative organism, or organisms in pure culture is essential to group as well as to type identification. The following procedure, which includes isolation of the hemolytic streptococcus type III in pure culture, is therefore presented:

The sputum is obtained and washed in the usual manner, diluted to 10 c.c. in sodium chlorid solution, and one and two loops are transferred to each of two tubes of 10 per cent. horse blood agar, which are poured into Petri dishes. This technic of isolation is the same as that used by Smith and Brown[2] and Smillie.[3] These are incubated for twenty-four hours.

The pneumococcus colonies—Type I hemolysis—may be easily differentiated by their small greenish halo of hemolysis from the streptococcus colonies, which are lance shaped and have a clear halo of hemolysis from 2 to 3 mm. in diameter, after an incubation of eighteen hours. Type I refers to the familiar *Streptococcus viridans* hemolysis; II and III to the alpha and beta types of hemolysis, respectively, of Smith and Brown. The medium should be almost on the border of being liquid, so as to permit of rapid growth and diffusion of hemolyzing products.

The next step in the procedure consists in picking four pneumococcus-like colonies and several streptococcus colonies and their transfer to slide ascitic fluid or serum agar smears. These agar smears are prepared by first placing a couple of layers of filter paper in the bottom of a large Petri dish, and on these a row of slides numbered with a diamond point. The Petri dish and its contents are then sterilized, after which the agar smears are prepared in the same manner as an ordinary blood smear. The picked colonies are transferred to these smears; the filter paper is then moistened to prevent the drying of the smears, and the Petri dish with its contents is incubated for from six to eight hours. The cultures so obtained on the slide agar smears are worked up into a homogeneous suspension with a platinum loop in the proper dilutions of pneumococcus Type I serum and streptococcus antiserum. These are of course controlled with dilutions of normal horse serum. This is essentially a "spot" agglutination. As pneumococcus Type I infection is the only one which can as yet be treated with serum, the identification of the other types may be eliminated from consideration, so far as the immediate bacteriologic diagnosis is concerned.

---

[2] Smith and Brown: Jour. Med. Research, 1914, **31**, 455.

[3] Smillie: Jour. Infect. Dis., 1917, **20**, 45.

The commercial antistreptococcus serum that we are now using agglutinates in twenty minutes in a dilution of 1:160 the strain of streptococci that were isolated from postmortem specimens. Serum should not be used until it has been tested against the known organism and its agglutinating titer determined.

This method of identification is short, is unencumbered with technical difficulties and gives reliable results.[4]

If the routine procedure for the typing of pneumococci is carried out in conjunction with the blood agar plate method for the identification of the hemolytic streptococcus, the slide agar smear procedure may be eliminated.

The clinical classification of the pneumonias is important, though less so than the classification from the bacteriologic point of view. From the findings here presented it would seem that the disease may be classified according to the causative organism into two main groups, primary pneumococcus and primary streptococcus pneumonia, and a subgrouping, primary pneumococcus and secondary streptococcus pneumonia. The pneumococcus pneumonias are further divided according to Types I, II, III and IV. As to the classification of the streptococcus according to type, however, this particular organism must await further investigation. We now have in stock about eighty antemortem and postmortem strains, and more than 700 from throat swabs which will be studied with the view of possible groupings among them.

VACCINATION AND SERUM TREATMENT

In pursuing this work the following points are to be considered:

(*a*) The advisability of vaccinating by the intravenous route all measles patients that are found to be hemolytic streptococcus carriers. The time elapsing between the measles onset and the appearance of complications is probably sufficient to allow for immunization by this method.

It was at first contemplated to vaccinate only those patients who proved to be carriers of hemolytic streptococci. But since a comparison between the findings of swab and of sputum examinations in a series of cases shows that 25 per cent. of the carriers may be missed when diagnosis depends on a single swab, all patients should be protected. These are divided into three groups, the ratio of carriers to noncarriers being kept the same throughout the work. Each patient in the first or vaccine group is receiving intravenously 100 million hemolytic streptococci on the first day and 500 million on the third day, then on the fifth day 1,000 million subcutaneously. The second or serum group should receive 10 c.c. of antistreptococcus serum intravenously. The third, or vaccine serum group, is receiving 2 c.c. of antistreptococcus serum with 250 million hemolytic streptococci intravenously on the first day, and two subsequent injections of vaccine of the same dosages and routes as those in the first or vaccine group. The sensitization of patients in the last two groups to horse serum is tested by an initial dose, and the mixture of vaccine and serum is tested in animals prior to its injection into the patients in order to rule out the presence of anaphylatoxic symptoms. No untoward symptoms have arisen from these intravenous doses of vaccine and serum. This dosage, however, in work in so initial a stage, must not be considered as definitely determined.

Sufficient time has not yet elapsed to permit of a report on this work. We realize, of course, that, at least from theoretical standpoints, there is objection to universal protective injections of antiserums; but as hemolytic streptococcus pneumonia is as fatal as plague, a limited investigation as here presented would seem justifiable in order to determine the most efficient method of protection. Owing to the fact that the hemolytic streptococcus is now incriminated as the killing organism in streptococcus pneumonia, as well as in a large percentage of so-called "lobar pneumonia" cases in our series it is now contemplated to institute the foregoing vaccine and serum treatment in the latter group of cases.

(*b*) The possibility of developing in the horse a high titer antihemolytic streptococcus serum; this to be used as a preventive as well as a curative. Horses are now being immunized by various methods of injections with the particular strains that have been isolated at necropsy from pure blood cultures.

(*c*) Since approximately 60 per cent. of pneumonias are type epidemic varieties, and at least a large percentage of the remainder hemolytic streptococcus pneumonias, the advisability of carrying out universal vaccination of troops by combining Types I and II pneumonias with the hemolytic streptococcus.

From the findings here presented it would seem that this organism (streptococcus) or group of organisms, is the causative organism in cases of bronchopneumonia, especially those following measles, and the immediate cause of death terminal infection in a certain percentage of lobar pneumonias.

We may now add that the pneumococcus pneumonias in and of themselves are not as fatal as heretofore believed, for in our series of necropsies on cases diagnosed as lobar pneumonia — though not large — the hemolytic streptococcus was isolated from either one of the serous cavities or from the heart's blood in all but two cases. One might ask whether or not this infection in the so-called type pneumonias is common in other parts of the country. We believe it is.

There is no reason to believe that the occurrence of hemolytic streptococcus pneumonia is limited to the Southern Department. This organism is of universal prevalence and has been isolated by us in cases of septic sore throat and scarlet fever in Massachusetts, from septic sore throat and the blood in two cases of fatal septicemia in Michigan, and from scarlet fever and one case of pleural effusion in California. From these facts, universal vaccination of all troops with this organism, as well as with type pneumonias, would seem advisable. From an epidemiologic standpoint, it may be said that this streptococcus is the so-called human type which is often transmitted to cows' udders by milkers, and spread through milk supplies.

This complicating organism is the immediate cause of death, and its terminal extension from the lung explains some of the failures of the antipneumococcus serum. From our series of necropsies it would seem that a specific antistreptococcus serum of a high titer applied in both groups of pneumonias—pneumococcus (in double infections) as well as streptococcus—would be the most efficient agent in reducing the present high mortality of these infections. Especially does this apply to the complicating pneumonias—after measles and scarlet fever — as well as the complications following lobar pneumonias.

---

[4] A short (one hour) method of identification of type pneumococci has been perfected by Captain Marshall A. Barber, S. C., U. S. Army, of the Southern Department laboratory, and this will be reported in a short time.

It may be regarded as an extremely important point in considering the serum treatment of type pneumonias to determine first whether or not the hemolytic streptococcus is coexistent with type pneumococcus.

In the series of necropsies here reported, the hemolytic streptococcus was found to be the immediate cause of death in 77 per cent. of the cases, it having been found in pure culture in serous exudates or the heart's blood in bronchopneumonia and in common with pneumococci in lobar pneumonia cases.

There is no infection more fatal than hemolytic streptococcus septicemia, and this complication as well as the less serious extension of the lung involvement into the pleural and pericardial sacs must be guarded against by well considered therapeutic treatment. If the invasion by the streptococcus can be limited to the lung tissue it is probable that the mortality from the pneumonias, streptococcus and pneumococcus complicated by streptococcus will be markedly reduced.

From a theoretical consideration, it would seem that vaccination would be of practical value in reducing both the case rate and the mortality in type pneumonias and in broncho streptococcus pneumonias, and especially in the pneumonias following measles as well as other complicating processes after measles.

Since vaccination experiments in animals have shown that a high degree of immunity against both streptococcus and pneumococcus infections can be produced, it would seem reasonable to conclude that a triple vaccine consisting of the hemolytic streptococcus and pneumococci Type I and II would give favorable results.

It may be added that universal vaccination against streptococcus infection should also protect against the complications incident to scarlet fever, as well as against the lung infections of streptococcus and complicated pneumococcus pneumonias.

Amendments to Sanitary Code in 1917.—The January *Bulletin* of the New York State Department of Health reviews the amendments to the Sanitary Code which have been adopted during the past year and calls special attention to the following:

Chancroid gonorrhea and syphilis were added to the list of diseases declared to be communicable; it was made obligatory on every physician, when treating a patient affected with any of these diseases to furnish such a patient with a circular of information approved by the State Commissioner of Health and to instruct them as to the precautions to be taken to prevent the communication of the disease to others. It has been made obligatory on every physician to report to his local health officer all persons bitten by suspected rabid animals and all cases of acute anterior poliomyelitis. In order to inform the local health officers of the occurrence of deaths from communicable diseases other than tuberculosis, it has been made the duty of the local registrar of vital statistics to report immediately to the health officer, the name, age and address of the deceased, whenever a certificate of communicable disease is received, and also the name of the physician who filed the certificate; it is also the duty of the health officer to ascertain whether such person was reported during life as being infected with a communicable disease. A model sanitary code for towns, villages, and third class cities was prepared and recommended for adoption by local authorities. The State Commissioner of Health was given authority to declare extracantonment zones about military camps, and provision has been made for the monthly inspection of such zones by health officers. Regulations were adopted providing for the inspection by health officers of boarding and lodging houses containing people affected with tuberculosis, and licenses are required of boarding houses making a business of boarding children under 12 years of age, away from their parents. More stringent regulations were adopted regulating the practice of midwifery.

A PLEA FOR A MORE FUNDAMENTAL METHOD IN MEDICAL TEACHING

ROBERT W. LOVETT, M.D. (Boston)
Major, M. R. C., U. S. Army
WASHINGTON, D. C.

The recognition of the specialties of medicine made by the Surgeon-General of the United States Army in the early months of the present war represents a step of importance in the progress of medicine, and will obviously promote the efficient care of the wounded. It must to a greater or less extent have an effect on the future of medicine, and it is not unlikely that it may modify medical education, especially as some of the medical schools have in the past few months had experience in the intensive training of groups of military surgeons in the special branches, an experience which in my case has modified extensively my views as to the best methods of teaching.

The experience mentioned has consisted in being associated with four such intensive courses, three at the Harvard Graduate School of Medicine and one at the Army Medical School in Washington. These courses were given to selected military surgeons to acquaint them with some of the fundamentals of orthopedic surgery. To attempt to do more than this in the four, six or eight weeks at our disposal seemed unwise, yet we had in even the shortest of the courses some 130 hours of instruction, far more than any undergraduate would receive in that specialty in any year of his medical course.

Many of these men knew no more orthopedic surgery than is taught in our regular medical school, while others had special experience; but the proposed intensive education naturally had to be adapted for those who knew least. The problem, therefore, was to teach these men as effectively as possible in the time at our disposal. The ordinary method of teaching undergraduates, which consists of instructing the students item by item in the various affections, looked inadequate and proved to be, so that after the first an attempt was made to teach the basic principles of orthopedic surgery and to illustrate these principles clinically.

As the plan apparently proved successful and was intensified in each succeeding course, it has seemed that it might perhaps have a bearing also on the question of undergraduate teaching in this and in other departments in medicine. The matter, therefore, is here discussed from the point of view of a teacher of orthopedic surgery, but with a definite feeling that it has a wider application. I am indebted to my colleague, Capt. Mark H. Rogers, associated with me in the Boston course, for much sympathetic help in the elaboration of the plan.

In the past it has been the custom in general to teach the specialty to the undergraduate by giving didactic or clinical instruction, recitations, or all of them in those different affections which, taken together, might be regarded as constituting orthopedic surgery. Thus scoliosis, clubfoot, the deformities of poliomyelitis, tuberculosis of the spine, flatfoot, torticollis, round shoulders, etc., were taken up one by one, described, demonstrated, illustrated, discussed and dismissed. This is the easy and the obvious way of teaching orthopedic surgery or any allied medical subject, but it is simply making the student, if he remembers all that he learns, into a medical encyclopedia with separate, unrelated blocks of information necessarily incomplete in number, because of the impossibility of covering every affection. Although this might pass, and has passed, unchallenged in the undergraduate curriculum, it did not stand the test of intensive instruction when instruction became an unusually serious and responsible business.

The plan was adopted of first taking up general principles, and then illustrating these clinically. It thus became the reverse of the so-called "case system," because the student first heard the principles stated, and after being grounded in them, was made familiar with their application. He did not, as in the "case system," learn to deduce his principles from clinical experience. It was felt that in training necessarily short, but which must be comprehensive, no matter how abundant the supply of clinical material might be, it was safer to ground the student in the fundamentals and teach him to apply them to patients. In this way he would, or should, be better able to approach a new and unusual condition which he had not met clinically.

For the carrying out of this plan it became necessary to arrange the subjects to be taught in groups. The different systems or structures of the body, the joints, the muscles, etc., seemed to offer the best basis of correlation, and in these groups were placed the affections of the different systems. The plan adopted for this method of teaching this specialty was as follows:

AFFECTIONS OF THE JOINTS

The anatomy of the joints was briefly spoken of, and their general structure, components and varieties described. The physiology of joints was alluded to, and attention called to the facts that use means increase of synovia, that muscles of normal strength are necessary for good joint function and stability, etc. Then came a short statement of the pathologic reaction of joints to trauma, infection or toxins, and it was shown that in the beginning joints react in the same way to the various abnormal influences; that first come hyperemia of the synovial membrane, swelling and increased secretion, and that from this point on one of four cases is generally followed: (1) recovery with a reversal of the acute process; (2) a chronic condition which is a prolongation of the acute; (3) suppuration, and (4) destruction or degeneration, perhaps leaving an ankylosis. Muscle atrophy was shown to be an early accompaniment of all joint affections, and muscle spasm was demonstrated as a reflex tonic contraction of articular muscles in painful and serious joint affections, while ankylosis was shown to be the result of destruction of some part of the joint and to be regarded as a cicatrix.

Cases of any joint affection were then shown, and the students, when possible by personal examination and questioning, were made to identify the general signs described above and to account for them on general pathologic principles. Etiology and special pathologic processes were not at this time discussed. Traumatic affections of joints were then taken up, and a few words said about the peculiarities of different joints in their reaction to trauma; for example, that in the knee the synovial membrane is accessible to examination, but that it is not so in the hip and spine, and that in the latter one must depend more on stiffness, malposition, etc. Cases of traumatic joint affections were then presented, general signs were demonstrated by the students, general conclusions and conclusions as to the pathologic process of the individual case were drawn, differential diagnosis was discussed, and a treatment was formulated to meet the pathologic needs of the individual case. Following this, infections of the joints were taken up and the pathologic peculiarities of tuberculosis described and demonstrated by specimens, lantern slides and roentgenograms. Clinical demonstrations followed along the same lines as those employed with traumatic affections. Acute infections, nontuberculous arthritis, syphilis, intermittent hydrops, hemophilia, etc., were taken up in the same way. Finally, ankylosis was further discussed and clinically demonstrated, positions desirable for stiff joints were elaborated, passive motion and ankylophobia were discussed, and the subject of joints was dismissed.

I had the feeling each time this one department was completed that the student had been furnished with an alphabet by which to spell out the conditions as he met them rather than an incomplete encyclopedia, the items of which he might or might not remember correctly. As this division of the subject has been dwelt on at length, the others may be mentioned much more briefly.

DISEASES AND AFFECTIONS OF THE BONES

The general structure of bone, its growth, regeneration and repair were taken up, and next came a consideration of the various pathologic processes affecting bones, with their peculiarities and characteristics, which were demonstrated clinically and by operations. This included acute and chronic osteomyelitis, syphilis, rickets, osteomalacia, fragilitas ossium, achondroplasia, Paget's disease, etc.

AFFECTIONS OF THE MUSCLES OR, MORE PROPERLY, THE NEUROMUSCULAR MECHANISM

The passage of a motor impulse from brain to muscle was described, the upper and lower neurons mentioned, and the distributing function of the synapse showed. The general laws of reflexes were next considered and the general phenomena of muscles discussed, it being pointed out that they are easily fatigued and stretched, always under tension unless paralyzed, and easily developed by exercise. It was then mentioned that the orthopedic surgeon, especially in the field, would have to deal with the deformities caused by focal cord lesions, and lesions of the cerebral motor area and of the peripheral nerves. The essential characteristics of each were pointed out.

The cord lesions were demonstrated, by means of patients, in acute poliomyelitis and fracture of the spine; cerebral lesions, in cerebral spastic paralysis; and peripheral lesions by obstetric paralysis.

STATIC AFFECTIONS

That muscular weakness far short of paralysis might cause deformity was pointed out. The mechanism and anatomy of the foot were described, and its abnormalities under unfavorable conditions of general health, overuse, bad shoeing and overweight were discussed and then clinically analyzed after the general principles had been elaborated. Bad attitude and scoliosis were taken up in the same way, after certain elementary considerations as to the mechanics of the spine and posture in general.

CONGENITAL DEFORMITIES

However comprehensive this or any scheme may be, a heterogeneous group of congenital deformities remains to be considered, and these apparently must be taught by the old itemized method after a short statement of our knowledge, or rather lack of knowledge, of the cause and mechanism of congenital deformities.

APPARATUS

In no part of the subject has the need of generalized instruction been more evident than in the question of apparatus.

This subject has generally been taught through a description by name, in connection with each condition, of some especial apparatus that is used for its treatment, for example, the Thomas splint for hip disease. For the subject of apparatus to be taught effectively, it must be approached in a broader way, and the student made to formulate in each pathologic condition the mechanical requirements, if any, based on the special pathology and his knowledge of joint physiology and mechanics. The student's general attitude is that tuberculosis of the hip requires a brace, the name of which he may or may not recall and of whose mechanical use he knows little or nothing. It is essential to have him learn to recognize that hip tuberculosis requires fixation or traction or both; that this need is determined by the activity and the acuteness of the process in the individual case; that there are many methods of obtaining these ends mechanically, and that the student should recognize the mechanical problem, the crudest way of meeting it, and then the elaboration of crude methods into light and efficient apparatus. This would give the man, especially in the military service, some resource in improvising apparatus, and make him more intelligent in the choice of a method. One would then teach that apparatus was of all kinds: "Wooden splints for fractures are apparatus; so is plaster of Paris. Iron, leather, celluloid, aluminum, papier mâché, etc., also may be. The purposes for which apparatus is used should be shown as being (1) for fixation; (2) for traction; (3) for protection or stilting, and (4) to correct deformity. In short, the student should be taught to state what he is trying to do in the individual case in mechanical terms, to work out the principle in crude material, and then be made familiar with accepted forms of apparatus suited to such a case.

RECONSTRUCTION

The question of the rehabilitation of the wounded man and his vocational training must be considered as a special subject, not only because the man disabled in war must be provided for, but also because our knowledge of the rehabilitation of war cripples must be applied later to industrial conditions, and the man crippled in industrial life will never in the future be neglected as he has been in the past.

The general principles on which the best reconstruction work is founded, and the selective aspect and the man's adaptability to a special job as well as the adaptation of the occupation to the individual, are unfolded.

The use of artificial legs and arms, their measurements and fitting, precautions to be taken with the stump and joints of the limb, adaptive additions to artificial limbs, and similar subjects are covered.

SUMMARY

It will be seen that the crude scheme just described covers all those affections which by the broadest possible interpretation can be included in orthopedic surgery, and that it groups them and gives the student connecting links on which to correlate his impressions, and makes a definite attempt to ground him in fundamentals and to teach him from these fundamentals to elaborate his own details. This method is probably in use in certain departments of medicine and perhaps by some men in all departments; but that it is not the common method would be generally admitted. In the intensive teaching of a special branch to mature men it has been most successful. It would seem as if the undergraduate approaching orthopedic surgery would emerge from his instruction a sounder man if this method were employed than if he merely received instruction in one item after another, however good that instruction might be.

The scheme as presented above is, however, incomplete, because much of the instruction advocated belongs to the departments of anatomy, physiology and pathology, and should be given in those departments and not in orthopedic surgery. However, instruction in most medical schools is imperfectly correlated, and it proved necessary to instruct the men in these special applications of anatomy, physiology and pathology because they did not know them well enough to make practical use of them, and the men in question came from many different schools.

A broader scheme, which it is not wise to advocate under war conditions, would point to a more effective correlation of work between the preclinical and the clinical departments in the medical school of the future, without in any way impairing the principle of proceeding from the general to the special as an educational principle.

Smoking and Rifle Shooting.—Some experiments were conducted by the National War Council of the Y. M. C. A. to determine whether smoking affected accuracy in rifle shooting. Smoking and nonsmoking students of the Y. M. C. A. College at Springfield, Mass., participated. In marking the skill of the shooters both the score and the deviation in score covering a certain number of shots before and after smoking were considered. In the first experiment without smoking, five shots were fired, then a rest of thirty minutes and five more shots. In the second, during the interval one cigar was smoked. In a third, two cigars were smoked during an interval of sixty minutes. In a fourth two cigarets were smoked. In the fifth the first experiment was repeated. The shooting was at a target from the prone position with a rifle shooting a 0.22 long cartridge. In the first experiment the group average was 38.1 and after resting, 41; before resting the total deviation was 9.23 per cent.; after resting, 7.04 per cent., a decrease in deviation of 12.8 per cent. After one cigar there was a loss of 4.8 in score and an increase in deviation of 24 per cent. After two cigars there was a loss in score of 6 per cent. and an increase in deviation of 26.4 per cent. After two cigarets there was a loss in score of 1.8 per cent. and a decrease in deviation of 1 per cent. In the last experiment, without smoking, but with a rest of thirty minutes, there was a gain of 13.2 in scoring and a decrease of 9.9 per cent. in deviation. The whole group decreased in efficiency after smoking, greater after two cigars than one, but less after the two cigarets than after the cigars. The smokers were affected the least by the smoking, but the nonsmokers were the more efficient after rest. The experiments indicate that soldiers and sportsmen would be better marksmen if they did not smoke.

STATE BOARD STATISTICS FOR 1917

ANNUAL PRESENTATION BY THE COUNCIL ON MEDICAL EDUCATION OF RESULTS OF STATE BOARD EXAMINATIONS

On pages 1074 to 1083 are three tables, A, B and C, giving in detail the results of the various state medical license examinations held during 1917. Full reports were obtained from all state licensing boards and were carefully verified.

Tables A and B, when read from left to right, show (*a*) the number of graduates appearing for examination in each state, (*b*) whether they passed or failed, (*c*) the total number examined during the year, (*d*) the number who passed, (*e*) the number who failed, (*f*) the percentage of failures, and (*g*) the number of states in which graduates of each school appeared for examination. Read from above downward, they give the results by states, showing (*h*) the number registered and rejected from each college, (*i*) the total number examined, (*j*) the total number registered, (*k*) the total number rejected, and (*l*) the percentage of rejections. The fact that the majority of graduates take the license examination in the state in which the college is located is shown by the dark diagonal zone made by the grouping of figures passing from the upper left to the lower right corner of each table. This shows also that the states in which low-grade medical schools are permitted to exist are themselves the recipients of the greater portion of the ill-trained output of such schools. These tables are worthy of careful study, since important deductions are possible. The marginal numbers will enable one to follow readily the line for any college.

Caution in Forming Conclusions

In making comparisons on the basis of these statistics, several factors should be kept in mind. The number examined is important, since, if all other conditions are equal, the larger the number of graduates examined, the more accurate is the finding. But other conditions are seldom equal. The number of states in which a school's graduates have been examined is important. The larger this number the more accurate will be the conclusions. Again, the character of the board making the examination and the methods employed are important factors to be considered, since some boards hold very careful examinations and include practical laboratory and clinical tests, or they may mark the papers more severely; while others, especially partisan boards, may be very lenient. In this connection it should be stated that, although conditions are undergoing a steady improvement, it is still true that the character of the license examination as usually conducted is such that graduates of colleges conducted largely by quiz-class methods may easily be successful in passing it. It is particularly important, in forming conclusions based on these statistics, to note for each college the states in which its graduates are not admitted to examination-information set forth with these statistics in Table D.

Graduates of All Years Examined in 1917

Table A shows the results for all candidates who took examinations in 1917, regardless of the years in which they graduated. This shows that altogether 4,730 candidates were *examined* last year, as compared with 4,850 in 1916, 5,313 in 1915, 5,570 in 1914 and 6,435 in 1913. There has been a steady decrease each year since 1906, when 8,035 physicians were examined. The decrease each year has been due largely to (*a*) the wider extension of reciprocity, and (*b*) the general diminution in the number of medical colleges, students and graduates. Of those examined this year, 14.1 per cent. failed, as compared with 15 per cent. in 1916, 15.6 per cent. in 1915, 21.6 per cent. in 1914 and 18.6 per cent. in 1913. This reduction in the percentages of failures indicates improved medical teaching, since there is reason to believe that methods of examination have not been relaxed but are more carefully conducted than formerly.

There were 89 medical colleges in the United States granting degrees in 1917 which had graduates examined, the same number as in 1916. There were 93 in 1915, 96 in 1914 and 99 in 1913. There has been a decrease of 64 since 1905, when 153 medical colleges in the United States had graduates examined. The figures regarding graduates of medical schools which have ceased to exist, either through merger or otherwise, have been included in the line for miscellaneous colleges.

Foreign graduates were examined in 16 states, the total number being 79, and of this number 37, or 46.8 per cent., failed. The largest number of foreigners examined in any state was 18 in New York, where 8, or 44.4 per cent., failed. Graduates of Canadian schools were examined in thirteen states, more appearing, naturally, in the border states. The figures for the Canadian colleges are given separately in order to show the number of candidates coming from each, and to show the successes of their graduates at the examinations. Altogether, 34 candidates from Canadian colleges were examined, of whom 8, or 23.5 per cent., failed. Of all Canadian colleges, the University of Toronto had the largest number examined. The highest percentages of failures were for Queen's University, 50.

Undergraduates and Osteopaths Examined During 1917

For the last two years no undergraduates have been examined. The number examined each year has constantly diminished since 1906, when 703 undergraduates were examined and 342 were licensed. Colorado is now the only state which will examine nongraduates, but only four have been licensed in that state in twelve years. The door has been closed, therefore, against the admission to practice of those whose medical training is known to be incomplete.

During 1917, in California, 151 graduates of osteopathic colleges were admitted to the regular examination for licenses as physicians and surgeons, and of this number, 73, or 48.3 per cent., were granted licenses. Of the total examined, 59 were given merely the "oral, practical or clinical" examination, and of this number, 24, or 40.7 per cent., were registered. (See Tables I and J.)

Recent Graduates Examined During 1917

Table B gives the results for graduates of 1913 to 1917, inclusive, examined during 1917. This table is important, since it deals with recent graduates, and is, therefore, the fairest basis for comparison between colleges. Of all candidates examined in 1917, 4,015, or 87.8 per cent., were recent graduates, and of this number, 10.1 per cent. failed, as compared with 12.9 per cent. for all candidates.

Old Practitioners Examined During 1917

Table C is so arranged as to show in comparison the results for graduates of all years (first column), for recent graduates (second coloumn), for graduates of 1912 and previous years (third column), and for graduates of 1917 (fourth column). Of the graduates of 1912 and previous years—"old practitioners"—564 were examined, and of this number 185, or 32.6 per cent., failed, as compared with 10.1 per cent. of failures for recent graduates. This high percentage of failures is due largely to the long time these candidates have been out of college and to the fact that they are required to take the same examination as recent graduates. Justice to these older physicians, who have been licensed, but who, for good reasons, desire to change their locations, is a strong argument for interstate reciprocity in medical licensure; for the use of practical examinations by which they may show their skill in diagnosis and treatment, and for special percentage allowances for years of active practice. The total number of these candidates is diminishing each year as

TABLE D.—NONRECOGNITION OF MEDICAL COLLEGES

This Table, Based on Official Reports, Shows the Numerous Pitfalls to be Avoided by Prospective Medical Students

Colleges marked (x) have been reported as not recognized by the states in the columns of which the letter appears.

Marginal Number	COLLEGE	Classification by Council on Medical Education †	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	Reported Non-Recognition by State Licensing Boards			Marginal Number

---

* Twelve medical colleges give only the first two years of the medical course.

† Classification revised to March 15, 1918.

1. Rated in Class C when last inspected—1912. Since then it has refused reinspection. Has united with the Chicago Hospital College of Medicine. Both are reported as not recognized by the Illinois Department of Registration and Education.

2. This college is an offshoot of the Eclectic Medical University, an institution rated in Class C. It is reported as not recognized by the Missouri State Board of Health.

3. Rated in Class C, June 3, 1912, and since Nov. 14, 1916, has refused to permit a complete reinspection by the Council's official inspector.

(x) According to official reports the licensing boards of the states thus indicated do not grant full recognition to, or have taken action refusing to admit to their examinations graduates of, the colleges marked by this letter—x.

CONCLUDED FROM PAGE 1073

increased reciprocity relations are established. As a rule, the states which do not have reciprocal relations with other states (as Florida, Montana, Massachusetts, Oregon and Washington, see Table J) examined the largest numbers of old practitioners.

Graduates of 1917 Examined During 1917

Table C also gives the results for the graduates of 1917 who were examined during the year by the state boards, and shows that 2,605, or 56.8 per cent., of all candidates examined during the year graduated in 1917, including three who graduated from Canadian medical colleges. Educational statistics show that the medical colleges of the United States graduated 3,379 students last year; therefore, 74.1 per cent. of all graduates in 1917 took examinations for license during that year. In some of the states, graduates in medicine are allowed to serve as hospital interns without first becoming licensed practitioners, which doubtless accounts for some of the remaining 25.9 per cent. Of the 1917 graduates examined, 149, or 5.7 per cent., failed. Of the 1916 graduates examined in 1916, 7.4 per cent. failed; of the 1915 graduates examined in 1915, 7.5 per cent. failed, and of the 1914 graduates examined in 1914, 12.7 per cent. failed. A steady improvement in recent years in the qualifications of medical graduates is apparent from these figures.

TABLE E.—COLLEGES GROUPED BY STATES

Showing the Number Examined and Percentage of Failures

All Colleges of	Graduates								State Rank According to the Number Examined	Rank According to Successes at Examinations
	Of All Years		Of 1913 to 1917		Of 1912 & Prev.		Of 1917

Total Ex. in 1917	4253	10.7	3937	9.5	316	25.6	2600	5.6		

This table gives data relating to the group of colleges in each state. For example, it shows that, of all the medical schools in Massachusetts, 283 graduates of various years were examined by state boards during 1917, and of this number, 14.1 per cent. failed. Of the 255 who graduated in recent years (1913 to 1917 inclusive), 11.7 per cent. failed; of the [illegible] graduated previous to 1913, 35.7 per cent. failed, and of the 165 [illegible] 6.1 per cent. failed.

[illegible] gives the rank of each state group of colleges according to the number of graduates examined. The Illinois group of colleges leads, having 772 graduates examined by state boards during 1917, followed by New York with 631, Pennsylvania with 416, Tennessee with 382, Massachusetts with 283, and Maryland with 206.

The last column gives the rank of each state group of colleges according to the success of the graduates at the examinations. It is interesting to compare the figures of these two last columns. While the Illinois group ranks first according to the number examined it ranks seventeenth in the success of its graduates at the examinations. While Tennessee ranks fourth as to the number examined, it ranks as the twenty-fourth in the success of its graduates at the examinations.

Nonrecognition of Medical Colleges

Table D shows for each college, from official reports, the states in which its diplomas are not given unqualified recognition. Nonrecognition is expressed by different terms in different states. Some boards list colleges as "in good standing" or "not in good standing"; some give them as "reputable" or "not reputable"; in New York full recognition is given only to colleges which are "registered," and in Michigan colleges are divided into groups, only those of Group 1 having full recognition. There are thirty states which do not register graduates of a medical college unless such graduates had completed at least two years of collegiate work prior to entering on the study of medicine. This table also shows the latest rating given to each college by the Council on Medical Education.

TABLE 1.—RECOGNITION OF MEDICAL COLLEGES (BASED ON TABLE D)

	Number of Colleges
Recognized by all state boards	55
Not recognized by 1 to 3 state boards	14
Not recognized by 8 to 24 state boards	13
Not recognized by 25 to 37 state boards	14
Total	96

From the point of view of the prospective student who may be selecting a medical college, the facts in Table D are of extreme importance. There are 55 medical colleges now having complete recognition in all states. There are 14 others for which the few instances of nonrecognition are due to certain technicalities in state board requirements. If the student gets his medical training in one of the remaining 27 colleges, he will find on graduation that his diploma is not recognized in from 8 to 37 states!

Without the information published in Table D, these state board statistics would be not merely incomplete—*they would be actually misleading.* For example, 30 graduates of the Kansas City (Mo.) College of Medicine and Surgery were examined in 1917. Of these, 27 (90 per cent.) were examined by the Arkansas Board of *Eclectic* Medical Examiners, and 3 were examined elsewhere, and 6, or 20 per cent., failed. Accordingly, this college would appear to belong among the average grade medical schools of the country. How different the picture, however, when the facts are known, as set forth in Table D, that this college is reported as not recognized *in its home state* and in 31 other states, and that for its very existence it depends on the acceptance of its graduates by the sectarian boards of Arkansas and Connecticut.

During the five years this table has been published, the percentages of fully recognized colleges were, respectively, 29.0, 32.3, 43.7, 65.6 and 57.3. This shows a decided improvement in the medical colleges. Forty state licensing boards, to some extent at least, are utilizing their legal power to refuse recognition to medical colleges which do not meet the requirements in the respective states. In the other ten

TABLE 2.—SOURCE OF CANDIDATES REGISTERED BY EXAMINATION

Graduates of	1910		1917	
	Number	Per Cent.	Number	Per Cent.
Class A *medical* colleges	3,870	67.7	2,237	69.6
Class B medical colleges	977	17.1	813	20.0
Class C medical colleges	292	5.1	255	6.3

Undergraduates	192	3.4	....	....
Totals	5,712	100	4,061	100

states, however, and in the District of Columbia, this table indicates that either the practice acts do not give the boards authority to enforce a requirement of reasonable standards, or else the boards are not exercising that authority. It is evident that if the graduates of low-standard medical colleges are not eligible for license in the majority of states, they will flock to the other ten which still grant them recognition. These ten states—Arizona, California, Idaho, Massachusetts, Nevada, Oregon, Tennessee, Utah, Washington and Wyoming—and the District of Columbia, therefore, are literally the dumping ground for the output of low-grade medical colleges, and will remain so until the licensing boards obtain the needed legal powers, or until the boards having the authority take action in the matter. Arkansas, Connecticut and Florida are also registering through their separate sectarian licensing boards graduates of medical colleges not recognized in the majority of other states.

TABLE 8.—FAILURE PERCENTAGES ACCORDING TO SOURCE OF APPLICANTS

Graduates of Medical Colleges in	1910 Examined	1910 Passed	1910 Failed	1910 Per Cent. Failed	1917 Examined	1917 Passed	1917 Failed	1917 Per Cent. Failed
Class A	4,318	3,870	448	10.4	3,046	2,827	219	7.2
Class B	1,268	977	291	22.9	997	813	184	18.4
Class C	479	292	187	39.0	395	255	140	35.4*
Miscellaneous	478	311	167	34.9	213	124	89	41.7
Foreign	108	70	38	35.2	79	42	37	46.8
Undergraduates	353	192	161	45.6	......	......	......	......

* Class C colleges at present, as a rule, are not recognized in from 27 to 37 states. The percentage, therefore, is the result of examinations by partisan boards and in states where the boards do not have, or are not using, the authority to refuse recognition.

Incidentally it should be stated that only such drafted medical students as are enrolled in "well recognized" medical colleges are permitted by the War Department to enter the Enlisted Reserve Corps and thereby be permitted to complete their medical training, and only those medical schools are considered as "well recognized" which are recognized by the majority of state licensing boards. It is evident, therefore, that no medical school shown in Table D will be considered as well recognized by the War Department if it is recognized by less than 50 per cent. of the state licensing boards.

SOURCE OF CANDIDATES REGISTERED BY EXAMINATION

Of the 4,061 physicians registered by *examination* in 1917, 2,827, or 69.6 per cent., graduated from Class A medical colleges; 813, or 20.0 per cent., were from Class B medical colleges; and 255,[1] or 6.3 per cent., were from Class C medical

---

[1] Of this number, 73 were graduates of osteopathic colleges who were licensed in California as "physicians and surgeons."

This table is especially interesting, since it gives data relating to the 30 larger medical colleges arranged according to the number of graduates examined. This allows of comparison between colleges having classes of nearly equal size. For the fifth consecutive year the Chicago College of Medicine and Surgery has had the largest number, the position having been held by the College of Physicians and Surgeons of Chicago in 1906, 1907 and 1912. In 1908, Jefferson Medical College had the highest number examined. In 1909, 1910 and 1911 the University of Louisville Medical Department had the largest number examined. The first place from the standpoint of the number examined, however, does not always mean first place from the standpoint of scholarship. Note the percentages of failures. The highest failure percentages are for the New York Homeopathic Medical College, 36.2; Meharry Medical College, 30.3; and University of Maryland School of Medicine, 19.8.

Of the 10 colleges having 100 or more examined, only 3 have failure percentages of less than 10, while the others stand out prominently with large failure percentages and for 5 the high percentages hold even of graduates of 1917.

Of the 20 colleges having between 50 and 100 graduates examined, sixteen had failure percentages of less than 10, and four had failure percentages between 10 and 20.

Not one of these colleges had a percentage of failures of 20 or above. The results indicate that colleges having classes of less than 100 students, as a rule, furnish a better training than those having larger classes.

The average percentage of failures for these larger colleges for graduates of 1912 and previous years was 29.4; for graduates of 1913 to 1917 inclusive (recent graduates), 10.4; for graduates of 1917, 6.5, and for graduates of all years, 11.7. Of the 4,253 graduates of the 89 colleges in the United States which had graduates examined by state boards in 1917, these larger (33.7 per cent. of all) schools furnished 2,913, or 68.5 per cent., of the graduates examined.

colleges. Of all candidates examined, 4.1 per cent. came from medical colleges which have ceased to exist and from foreign medical colleges. A comparison of these figures with the results for 1910, as shown in Table 2, will be interesting. The differences would be greater if the classification in 1910 had been as strict as that in 1917. It is interesting to note that in 1910, 3.4 per cent. of all candidates were undergraduates. In 1916 and 1917 not a single undergraduate was registered.

Table 3 will also be interesting, in that the failure percentages of candidates coming from the various groups of colleges support the classifications. It will be noted that graduates of Class A medical schools had a much lower

---

* These two colleges are reported as not recognized by the licensing board of the home state—Missouri—and they *could not* exist were it not for their being recognized elsewhere.

In this table the graduates of *each* college who were examined in the state in which the *college* is located are grouped in one column, while graduates of that college *examined in other* states are in another column. For example, under Louisiana, this table shows that of the 61 graduates of the Tulane University School of Medicine who were examined by state boards during 1917, 35 were examined in Louisiana, of which number 34 passed and 1, or 2.9 per cent., failed, while 26 were examined in other states, of which number 25 passed and 1, or 3.8 per cent., *failed*.

This table shows that in many instances the graduates *have* better chances of passing *examinations* in the state in which their colleges are located than they have elsewhere. This should always *be considered* in making comparisons between colleges. A low standard college by having all its graduates examined in the home state, or *by* a partisan board, may show a lower percentage of failures than a college of much higher grade which has graduates *examined* by several *states*.

The heavy-faced *figures give* the results by states. The first column of heavy-faced figures, preceded by the + and — signs, shows the differences between the percentages of examination in the *home state* and the examination elsewhere. The plus sign indicates that graduates have better chances of success in the state where the colleges from which they *graduated are* located; the minus sign indicates that the chances are better elsewhere. The most marked variations in 1917 were in the examination of the graduates of the colleges of Oklahoma, 62.5 per cent.; Tennessee, 25.9; Georgia, 25.7; Michigan, 23.8; Nebraska, 22.2; *Missouri*, 22.0; *Vermont*, 21.1, and Maine, 20.0, in all of which the chances of the graduates were better in the home state. The marked variations where the graduates' chances were better *elsewhere* were in South Carolina, 14.3, and New York, 8.5 per cent.

The totals show that, on the average, the chances of success were 7.7 per cent. better if the graduate took the *examination* in the state where his college was located.

percentage of failures than graduates of colleges in Classes B and C. In this connection it should be stated that the percentage of failures for Class C medical colleges would doubtless be higher except for the fact that graduates of several of these colleges were examined largely, if not entirely, by partisan or sectarian boards, and not by single boards which examine graduates of all schools. It should be remembered also that the graduates of Class C colleges, as a rule, are refused examination by all but a few state boards, and that in the latter, as a rule, the examinations are not as severe as in the other states.

STUDY OF TOTALS AND PERCENTAGES

A study of totals and percentages as compared with previous years is of interest. The total examined in 1917—4,730—is the lowest number of candidates examined for license in any year since the compiling of these statistics began. (See Table 4.) The number examined was 120 less than in 1916, 583 less than in 1915 and 3,305 less than in 1906, when 8.035 candidates were examined. Statistics regarding physicians licensed in the various states by reciprocity and by other methods are given in Tables I, J, K and L. By all methods—examination, reciprocity, under exemption, etc.—5,423 physicians were licensed during 1917, or 38 less than in 1916, 449 less than in 1915, and 2,442 less than in 1906, when 7,865 physicians were licensed.

TABLE 4.—TOTAL RESULTS

Other deductions from the larger tables presented in Tables E to H are worthy of special study.

STUDY OF COLLEGES BY STATE GROUPS

Table E gives the results for the group of colleges located in each state. It shows what states are furnishing the largest number of physicians, and the failure precentages indicate the kind of training these colleges are furnishing, so far as may be judged from the results of state board examinations. Of the thirty-two states having medical colleges which grant degrees, twelve furnished 100 or more candidates examined, six states furnished more than 200 each, and four furnished over 300 each. Illinois furnished 772 graduates, the largest number, followed by New York with 631, Pennsylvania with 416 and Tennessee with 382. Of the thirty-two groups of colleges, twenty-two had failure percentages of less than 10 per cent., nine had failure percentages between 10 and 20, and only one had 20 per cent. or more of failures. The highest failure percentage was obtained by the Tennessee group, with 20.6. Other deductions are given in the legend to the table.

STUDY OF LARGER COLLEGES

Table F is also based on the three large tables, and gives the results of state board examinations as they affect the thirty largest medical colleges. Although these colleges represent 33.7 per cent. of the 89 medical colleges in the United States having graduates examined, they furnish 68.5 per cent. of all candidates for license coming from medical schools of the United States. This table shows, however, that the graduating of large classes by a medical college does not prove excellence of teaching, since two of the colleges having 100 or more examined have high failure percentages. The larger the college from the standopint of students and graduates, the more serious is inferior teaching ability, as indicated by a high failure percentage. In fairness both to

This table gives the number of candidates registered and rejected on examination by each state during each of the last five years. The last four columns give the totals for the five years and the percentage rejected by each state.

Four states registered over 1,000 candidates by examination in the five years, these being New York, Illinois, Pennsylvania and Massachusetts. Over 2,000 were registered in only two states, New York with 2,753 and Illinois with 2,494. Altogether 22,202 physicians were registered by examination in five years, an average of 4,440 each year.

The seven highest percentages of rejections for the five years were in Alabama, 36.3; South Carolina, 35.8; Connecticut, 29.5; Oregon, 29.2; North Dakota, 28.7; Tennessee, 28.1; and Montana, 28.0. Until 1916 Massachusetts, Oregon and Tennessee included nongraduates among those examined during the last five years, and for that reason would be expected to have higher percentages rejected. On the other hand, in several states the boards refused to recognize certain colleges and eliminated many candidates prior to the examination by a careful scrutiny of credentials and as a result the percentages of failures at the examinations are lower than otherwise would be the case. For example, Ohio rejected only 3.7 per cent. of those who took their examinations, but graduates of nineteen medical colleges are not eligible for admission to the examinations. This table therefore should be studied in connection with Table D.

The lowest failure percentages were in Wyoming, 1.7; Vermont, 2.5; Michigan and Iowa, each 2.9; Ohio, [illegible] and Nebraska, 3.9

medical students and to the public, such schools should strengthen their teaching facilities or reduce the size of their classes.

Results in Home States and Elsewhere

Table G is of much interest, because it shows for each college the results of examinations in the state in which the college is located, as compared with the results of examinations in other states, where there is less probability of local influence. Of the 3,938 recent graduates examined in 1917 who came from the eighty-nine medical colleges of the United States which had graduates examined, 2,538, or 64.5 per cent., took their license examinations in the states in which were located the colleges from which they graduated. Of this number, 7.2 per cent. failed on the average, whereas, of the 1,024 graduates examined in other states, 14.9 per cent. failed. This would indicate that, on the average, the student has 7.7 per cent. better chances of passing the license examination by taking it in the state in which the college is located. Of the medical colleges located, respectively, in Oklahoma, Georgia, Nebraska, Missouri, Vermont, North Carolina and the District of Columbia, all graduates who were examined in the home state passed. On the other hand the graduates of the colleges of the above states, when examined in other than the home state, failed in the following percentages, respectively: 62.5, 25.7, 22.2, 22.0, 21.1, 16.7 and 10.0. Attention is called to the glaring fact that thirty-six graduates of two low-grade medical colleges of Missouri—who were not admitted to the examinations in their home states because those colleges were not, and still are not, recognized in Missouri—were admitted to examinations by the Eclectic Boards of Arkansas and Connecticut, and twenty-six of them passed and were granted licenses to practice. The people of Arkansas and Connecticut should be made aware of this fact. It is they who will suffer and not the people of Missouri.

Totals	3609	379	73	1279	83	5423

This table shows the total number registered during 1917 in each state by the various methods. The first three columns show those registered by examination: the first column showing the recent graduates registered, the second column the old practitioners (graduates of 1912 and previous years) and the third column shows those licensed who were graduates of institutions not generally recognized as medical colleges. The fourth column shows the number licensed through reciprocity and the fifth column shows those licensed under various exemption clauses in the practice acts, such as because of national fame or by recognition of diplomas (New Mexico). California granted the physician's license to 73 out of 151 applicants who graduated from osteopathic colleges. Of these, 24 were given merely an "oral, practical or clinical examination."

It is interesting to note that as a rule states which registered large numbers through reciprocity, New Jersey, Oklahoma and Michigan, for example, examined very few old practitioners. The large registration through reciprocity in California is due to the liberal provision in the recent medical practice act providing for the recognition of licenses granted in other states. There were no reciprocal registrations reported for thirteen states, including Alaska.

The last column shows the total number of physicians registered by all methods in each state during the year. Only three states registered over 300 each, these being New York, 635; Illinois, 520, and California, 440. Seventeen states registered less than 50 each. The largest registration was 635 in New York and the smallest was 2 in Alaska. The total registered by all methods was 5,423, a decrease of only 38 below the total registered in 1916.

Total Results for Five Years

Table H shows the number registered and the number rejected in each state for each of the past five years. A comparison of this table with the statistics in the last educational number of The Journal (Aug. 18, 1917, p. 598, Table 12) shows—what would be expected—that the states having the largest number of medical graduates examined the largest number of physicians. New York leads, having examined 3,597 candidates in five years, followed by Illinois with 2,958. The five states having the next highest numbers are Massachusetts with 1,382, Pennsylvania with 1,278, Tennessee with 1,184 and Missouri with 1,027.

Total Registration in 1917

The tables thus far described have referred only to the results of examinations and to those registered on that basis. Table I, however, shows the total number who received licenses in each state, including those registered by examination, by reciprocity and under various exemption clauses. Altogether 5,423 physicians were registered by all methods during 1917, as compared with 5,461 in 1916, 5,872 in 1915, 5,797 in 1914 and 7,865 in 1906. There has been a constant decrease in the totals licensed by all methods until 1915, when there was an increase of 79. In 1917 the total registered was 38 less than in 1916 and 449 less than in 1915. By reciprocity or under exemption clauses, 1,362 were licensed in 1917, as compared with 1,338 in 1916, 1,386 in 1915, 1,427 in 1914 and 1,265 in 1913. No undergraduate has been registered in any state during the last two years.

Over 100 were registered by all methods in seventeen states, over 200 in seven and over 300 in three, the largest numbers registered being 635 in New York, 503 in Illinois and 440 in California. Of those licensed in California, 204, or 46.4 per cent., were registered by the endorsement of licenses granted by the boards of other states. California also registered as physicians and surgeons 73 graduates of osteopathic colleges.

Medical Training of Applicants Licensed

Table J is of special interest, since it shows for each state the character of the medical training of the candidates licensed during 1917. Of the 5,423 candidates licensed, 4,061 were by examination and 1,362 were by reciprocity or on presentation of acceptable credentials. In considering the colleges from which reciprocal candidates graduated, the classification is not applied to any one who graduated prior to 1907 when the first classification of medical colleges was completed by the Council on Medical Education. Of the 4,061 candidates licensed by examination, 2,827, or 69.6 per cent., were from Class A schools; 813, or 20.0 per cent., were from Class B schools, 255, or 6.3 per cent., were from Class C schools, and 166 were graduates of colleges which merged with others, or became extinct prior to 1907. Among the graduates of Class C schools are included 73 graduates of osteopathic colleges who were granted the physician and surgeon's license in California. Of the 1,362 candidates licensed by reciprocity, 603, or 44.3 per cent., graduated prior to 1907, and are, therefore, included among miscellaneous, or unclassified colleges; 542, or 39.8 per cent., were graduates of Class A medical schools; 175, or 12.8 per cent., were graduates of Class B schools, and 42, or 3.1 per cent., were from Class C schools. Altogether, of the 5,423 graduates registered in 1917, 3,369, or 62.1 per cent., were graduates of Class A medical schools; 988, or 18.2 per cent., were from Class B schools, 297, or 5.3 per cent., were from Class C schools, and for 769, or 14.4 per cent., the colleges are unclassified.

As will be noted, the largest numbers of Class C graduates were licensed in California, with 88; Missouri, with 61; Illinois, with 40, and Arkansas, with 26. All but one of the Class C graduates registered in Arkansas were licensed by the Eclectic board.

Illinois registered 273 Class B graduates, the largest number, followed by California with 97, Tennessee with 63, New York with 57 and Oklahoma with 52. Arkansas, California, Illinois and Oklahoma licensed more graduates of Class B and Class C colleges than graduates of Class A medical schools.

Only Class A graduates were registered either by examination or reciprocity in New Hampshire and Rhode Island.

It is evident that in several states particularly, more care should be taken in the recognition of medical colleges, or better methods of examination should be adopted which will provide better safeguards against those not having adequate education.

Table K gives those registered without examination on presentation of satisfactory credentials, which included a license issued by some other state. This is commonly referred to as "reciprocity," which conveys the idea that the state

[1] Of the 111 physicians licensed in Arkansas, the Regular Board licensed by examination 22 Class A, 22 Class B, and 9 miscellaneous graduates and by reciprocity 5 Class A, 10 Class B, 1 Class C, and 14 miscellaneous graduates, a total of 83. The Eclectic Board licensed by examination 2 Class B and 25 Class C graduates, a total of 27. The Homeopathic Board reported no candidates licensed by examination and only one (miscellaneous) by reciprocity.

[2] Of the 83 graduates of Class C colleges licensed in California, 73 were graduates of eight osteopathic colleges which are not generally recognized as medical colleges by state licensing boards, and only one of the colleges has been reported so recognized by the California board. Altogether 151 osteopaths were admitted to the examination for licensure as physicians and surgeons and 73 were so licensed.

This table shows the classification of the colleges from which most of the physicians graduated who were licensed in 1917. Graduates of colleges which became extinct prior to 1907 who were examined, and are reciprocity licentiates who graduated prior to 1907, are unclassified and included under "miscellaneous" since it was in 1907 that the Council on Medical Education completed its first classification of all medical colleges.

It will be seen that nine states accepted Class C graduates through reciprocity where they did not license any by examination. On the whole, however, more were licensed by examination than through reciprocity.

By both examination and reciprocity, the largest numbers of Class C graduates were licensed in California, 88 (including 73 osteopaths); Missouri, 61; Illinois, 40; Arkansas, 26 (25 were licensed by the Eclectic Board); and New York, 17. The largest numbers of Class B graduates were licensed in Illinois, 273; California, 97; Tennessee, 63; New York, 57; and Oklahoma, 52.

Of all physicians licensed, 3,369, or 62.1 per cent., were graduates of Class A medical schools; 988, or 18.2 per cent., from Class B schools; 297, or 5.3 per cent., from Class C schools, and 769, or 14.4 per cent., from miscellaneous colleges.

This table shows the number of physicians registered by each state through reciprocity during 1917. Read from left to right, it shows the total number of physicians registered through reciprocity in the state named and the number of such candidates coming from the states named at the top of the various columns. Read from above downward, the figures show the number of physicians who left the state named at the head of the column and went to each of the states named in the corresponding lines, and at the bottom, the total number of *candidates leaving the state to go elsewhere.* For example, read from left to right, the table shows that New Hampshire registered twelve candidates through reciprocity in 1917 and that, of these candidates *7 came from Massachusetts, 1 from New Jersey, and 2 each from* Rhode Island and Vermont. Read from above downward the table shows that from New Hampshire 2 candidates went to California, 1 each to Kansas, Kentucky *and* Maine, *and 2 to* New Jersey, the total leaving the state to go elsewhere being 7. The line at the bottom shows in what states physicians who were registered through reciprocity obtained their original licenses. *From Illinois 170 candidates, the largest number,* obtained their original licenses. The next largest numbers came from Missouri with 84, New York with 83, Tennessee with 66, and *Pennsylvania with 62.*

Totals	1223	1355	1314	1271	1279	6442

This table shows that 6,442 candidates were registered through reciprocity during the last five years. Registration by reciprocity gradually increased from 1905 to 1914, since which time there has been a gradual decrease as the total of physicians licensed by other methods has decreased. A study of the totals for the different states shows that of the 6,442 registered during the five years 920, or 14.3 per cent., obtained their original licenses in Illinois. The states furnishing the next highest numbers are Missouri, 440; New York with 411, Pennsylvania with 387, Ohio with 262, Tennessee with 247, and Michigan with 242. New York could easily lead Illinois but reciprocal relations have been established with only seven other states.

Seven states — Connecticut (regular board), Florida, Massachusetts, Montana, Oregon, Rhode Island, and Washington — do not have reciprocal relations and would not appear in this table except for the fact that some states, like California, Colorado, Delaware, New Hampshire, New Jersey, and North Carolina will accept a physician's credentials if satisfactory, whether the state issuing the orginal license returns the favor or not.

which accepts the license of another must be granted the same courtesy by the state issuing the original license. The term does not always apply, however, since some state boards —Arizona, California, Colorado, Delaware, Maryland, New Hampshire, New Jersey and North Carolina as examples— accept the physician's credentials, if satisfactory, whether or not the state board issuing the original license returns the favor. Had not reciprocal relations been established by the thirty-seven states shown in Table K, 1,269 physicians—many of whom have been in practice for ten or more years—would have been compelled to undergo the ordeal of a second trying examination.

Table L shows in what states were granted the original licenses of those who were registered elsewhere under the reciprocity provision during the last five years. Of the 6,432 physicians licensed through reciprocity during the last five years, the largest number coming from any one state was 914, who obtained their original licenses in Illinois. Although New York has a larger number of medical college graduates each year than Illinois,[1] only 411 physicians obtained original licenses in New York and registered elsewhere through reciprocity in the last five years. This is accounted for by the fact that Illinois has reciprocal relations with twenty-two other states, while New York has established such relations with only seven.

IMPROVED STANDARDS OF LICENSURE

Table M shows the states which have adopted one or two years of college work as a minimum standard of preliminary education for those who seek the license to practice medicine in those states. The first and third columns show, respectively, when the one year and the two years of premedical college work affects students matriculating in medical colleges, and the second and fourth columns give the years in and after which all graduates are affected by the increased requirements. This table shows the remarkable progress which has been made in state board requirements since 1908, prior to which no state was requiring more than a four-year high school education as the minimum standard of preliminary education. As will be noted, there are now thirty-eight states which have adopted the higher standard, and of these, thirty require as a minimum *two years* of premedical college work. It is understood that in every instance the one or two years of collegiate work must have included courses in physics, chemistry and biology.

In Table N the advance in standards of licensure is shown for all states since 1904. The most marked increase is in regard to the requirement of collegiate work in thirty-eight states as referred to in Table M. The next greatest increase (thirty-five) is in the number of states—now forty—which are refusing to recognize low-grade medical colleges. Although, as shown in the third column, marked improvements have been made in state requirements for licensure, nevertheless, as indicated by the last column, there is still room for further improvement. The greatest needs are for a wider adoption of the requirement of the hospital intern year, the standard of two years of premedical college work, and a more general and larger use of practical tests in the examinations.

TABLE N.—ADVANCES IN STATE LICENSE REQUIREMENTS IN FOURTEEN YEARS

Requirement or Provision	States Having Provision for			States Still Having No Provision for
	1904	1918	Increase	
Preliminary Education—				
Any requirement	20	46	26	3[1]
A standard four-year high school education or higher	10	44	34	5[2]
One year or more of college work	0	38[3]	38	11
Two years of college work as a minimum	0	30[3]	30	19
That all applicants be graduates of a medical college	36	49	13	0
That all applicants undergo an examination for license	45	48	3	1[4]
Requirement of practical tests in the license examinations	1	16	15	33
Hospital intern year required	0	7[5]	7	42
Full authority by board to refuse recognition to low-grade colleges	14	43	29	6[6]
Boards refusing to recognize low-grade colleges*	5	40	35	9[7]
Reciprocal relations with other states	27	41	14	8[8]
Single boards of medical examiners	36	42	6	7[9]

* In three states, Arkansas, Connecticut and Florida, each of which has three separate boards, only the regular (nonsectarian) boards have refused recognition to low standard medical colleges.

1. District of Columbia, Massachusetts and Wyoming.
2. Idaho, Oregon and the states named in Footnote 1.
3. See Table M.
4. New Mexico.
5. Pennsylvania, 1914; New Jersey, 1916; Alaska, 1917; North Dakota and Rhode Island, 1918; Illinois, 1921, and Michigan, 1922.
6. District of Columbia, Idaho, Massachusetts, Oregon, Utah and Wyoming.
7. California, Nevada, Tennessee and the states named in Footnote 6.
8. Arizona, Connecticut, Florida, Massachusetts, Montana, Oregon, Rhode Island and Washington. To this list should be added the outlying territories of Alaska, Canal Zone, Philippine Islands and Porto Rico, which have no provision for reciprocity.
9. Multiple boards still remain in Arkansas, Connecticut, Delaware, District of Columbia, Florida, Louisiana and Maryland.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners, which was organized in 1915, consists of fifteen members, including the Surgeon-Generals of the Army, Navy and Public Health Services, and one other representative of each of those services, three representatives of the state medical licensing boards and six members appointed at large. Up to December, 1917, three examinations had been held, the first in October, 1916; the second in June, 1917, and the third in October, 1917. The first two were held in Washington, and the

---

[1] See Table 12, THE JOURNAL A. M. A., Aug. 18, 1917, p. 544.

Chicago. At these three examinations altogether fifty applicants were examined, of whom thirty-six passed and fourteen failed, the percentage of failures being 28 per cent.

Date of Examination	Where Held	Total Examined	Passed	Failed	Percentage Failed
October, 1916	Washington	10	5	5	50.0
June 1917	Washington	12	9	3	33.3
October, 1917	Chicago	28	22	6	21.5
Totals		50	36	14	28.0

Twelve medical schools were represented and the results were as follows:

College	Total Examined	Passed	Failed	Per Cent. Failed
Howard University School of Med.	1	0	1	100.0
Atlanta Medical College	1	1	0	0.0
Northwestern Univ. Med. School	11	8	3	27.3
Rush Medical College	20	16	4	20.0
State Univ. of Iowa, Coll. of Med.	1	0	1	100.0
Johns Hopkins Univ. Med. Dept.	4	3	1	25.0
Med. School of Harvard Univ.	3	3	0	0.0
Univ. of Michigan Med. School	2	1	1	50.0
Columbia Univ. Coll. of P. and S.	1	1	0	0.0
Univ. & Bellevue Hosp. Med. Coll.	1	0	1	100.0
Univ. of Penn. School of Med.	4	3	1	25.0
McGill Univ. Faculty of Med.	1	0	1	100.0
Totals	50	36	14	28.0

Holders of certificates from the National Board will be registered without further examination in Colorado, Delaware, Idaho, Kentucky, Maryland, New Hampshire, North Carolina, North Dakota, Pennsylvania, Rhode Island and Vermont. When the permanency of the National Board is established and the high character of its examinations is more generally recognized, it is quite probable that its certificate will be recognized by the licensing boards of a larger number, if not of all states.

In Conclusion

In the gathering and publication of these statistics, the endeavor has been to give a fair presentation of facts, a knowledge of which is always beneficial. This annual presentation of the results of state license examinations has had a powerful influence on medical education and medical licensure in this country. We reiterate our acknowledgments to the state licensing boards for their ready cooperation and the complete reports which have been furnished. For the verification of all figures the reports and data furnished by medical colleges have been of much value. We have no doubt that the information here published will be of service not only to the medical colleges and to the state boards, but also to the public, since the end-result is better qualified physicians.

RECOGNITION OF EXAMINATION OF NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners was organized in 1915. It is a voluntary organization, the object of which is to conduct examinations of physicians so thorough as to prove without doubt their qualifications for the practice of medicine. The value of its certificates, aside from a qualification of merit, depends on the recognition given to it by state medical licensing boards. Such recognition has already been given, or assured, by the licensing boards of the following eight states:

Colorado
Delaware
Idaho
Kentucky
Maryland
New Hampshire
North Carolina
North Dakota
Pennsylvania
Rhode Island
Vermont

It is hoped that the certificate will eventually receive universal recognition.

A successful applicant may enter the Reserve Corps of either the Army or Navy without further professional examination if his examination papers are satisfactory to a board of examiners of these services. The certificate of the National Board will also be accepted as qualification for admission to the Graduate School of the University of Minnesota, including the Mayo Foundation.

The board consists at present of fifteen members, including the three Surgeon-Generals of the United States Army, Navy and Public Health services and one other representative from each of those services, two representatives of state licensing boards and seven members appointed at large. As soon as expirations of terms of office will permit, there are to be three representatives of state licensing boards and six members appointed at large. The three Surgeon-Generals serve as long as they hold their respective offices, and thereafter their places will be filled automatically by their successors. The other twelve members were divided by lot into three groups of four, their terms being two, four and six years. Hereafter all appointments will be for a term of six years. The personnel of the board at present is as follows:

Admiral William C. Braisted, Surgeon-General, United States Navy; Surgeon-General William C. Gorgas, United States Army; Surgeon-General Rupert Blue, United States Public Health Service; Commander Edward R. Stitt; Col. Louis A. LaGarde; Assistant Surgeon-General William C. Rucker; Dr. Victor C. Vaughan; Dr. Horace D. Arnold; Dr. Austin Flint; Dr. Walter L. Bierring; Dr. Henry Sewell; Dr. E. Wyllys Andrews; Dr. Louis B. Wilson; Dr. Herbert Harlan, and Dr. Isadore Dyer.

The examinations of the board are held in Washington, D. C., and other large cities. The subjects of the examination and their values are: anatomy, 100; physiology, 75; chemistry and physics, 75; pathology and bacteriology, 100; materia medica, pharmacology and therapeutics, 75; medicine, 200; surgery, 200; obstetrics and gynecology, 100; hygiene and sanitation, 50; medical jurisprudence, 25. The passing grade is 75 per cent.

The first two examinations were held in Washington, D. C., Oct. 16-20, 1916, and June 13-21, 1917, respectively. The third examination was held in Chicago, Oct. 10-18, 1917, and the fourth in New York City, Jan. 9-17, 1918. Examinations are now being held at Fort Oglethorpe, Ga. (April 8-19), and at Fort Riley, Kan. (April 8-25). The only fee is $5.00 for registration. There is no examination fee.

The educational requirements of applicants are (*a*) a four-year high school course; (*b*) two years of acceptable college work, including courses in physics, chemistry, biology and a modern language; (*c*) graduation from a medical school rated in Class A by the American Medical Association; and (*d*) a year spent in an acceptable hospital as an intern or in a laboratory. These requirements apply to graduates of medical schools in 1912 and thereafter. The board may accept equivalent credentials of applicants who graduated prior to 1912. Credentials must be presented to the board prior to the examination sufficiently early to permit of investigation.

For further particulars address Dr. J. S. Rodman, secretary, 310 Real Estate Trust Building, Broad and Chestnut streets, Philadelphia.

RECOGNITION OF GOVERNMENT EXAMINATION

The examination given under federal authority, which should be generally recognized by all state licensing boards as a qualification for license to practice medicine, is that given to medical officers of the United States Army, Navy, and Public Health Service. In fact, retired officers from the services mentioned are now eligible to receive licenses without further examination in

Alabama
California
Colorado
Illinois
North Dakota
Porto Rico
Virginia
Wisconsin

The Simulation of Disease.—In an article in *Public Health Reports,* Nov. 9, 1917, A. G. Dumez, of the Public Health Service, gives a long list of diseases and skin lesions of various sorts which have been found to be artificially produced by means of various drugs, chemicals, and septic materials, by persons who attempt to evade military duty. The various troubles, some of the means by which they are produced and the methods of detection are set forth in the article. This information is important at the present time for the use of military medical examiners and exemption boards.

STATISTICS OF STATE BOARD EXAMINATIONS

We publish this week, for the fifteenth consecutive year, tabulated statistics based on official reports of examinations conducted by state medical licensing boards. Reports have been received from all state boards; thus the statistics are complete.

IMPORTANCE OF THESE STATISTICS

The importance of these statistics may not be appreciated by the casual reader. In our fifty states there are fifty different medical practice acts, providing for sixty-one different licensing boards, no two of which entirely agree in the details either of the methods followed or of the standards enforced. In some states the public is well protected against illiterate and incompetent physicians; in others because of poor laws, or because of the existence of two or more independent and conflicting boards, the right to practice medicine may be secured even by grossly incompetent applicants. The publication of accurate information is the only way in this country to secure the correction of such conditions. The statistics published this year will, we hope, prove to be as effective toward this end as have the statistics of previous years.

FACTS REGARDING EACH STATE

The tables show for each state the number of candidates that appeared for examination, the colleges from which they graduated, the total number registered, and the total number and percentage of those rejected. The tables permit comparisons of the totals and the percentages of one state with those of other states. The figures show that if a state harbors a low-grade medical college, the people of that state are the principal sufferers. They also reveal conditions in a few states to which special attention should be called. For instance, 151 graduates of osteopathic colleges were admitted to the examinations in California, and seventy-three were licensed to practice medicine and surgery in that state! Again, two low-grade colleges, located at Kansas City, Mo., are not recognized by the Missouri state board and, hence, their graduates cannot secure licenses in that state. Nevertheless, thirty-five graduates of those colleges were examined by the Eclectic licensing boards of Arkansas and Connecticut, and twenty-eight (twenty-five in Arkansas and three in Connecticut) passed and were given licenses to practice medicine! The people of Arkansas and Connecticut evidently believe in sectarian boards; the facts just related may lead them to change their belief.

Table G shows that, as a rule, the examinations of state boards are more lenient toward graduates of medical schools located in the respective home state than toward graduates of colleges located in other states. Table H shows that the percentage of applicants rejected by some states is high, while in other states low percentages are rejected. A low percentage may mean that a state board is lax in its duty and has not established adequate safeguards against incompetent physicians. This may be determined by a study of Tables D and J. If a state board is admitting to its examinations graduates of any and all colleges, osteopathic or otherwise, then a high percentage of rejections would be expected. If, however, the board has refused to "recognize" low-grade colleges and is admitting to its examinations only the graduates of the better institutions, then a low percentage of failures might result even with thorough examinations.

Tables I, J and K show, respectively, the totals registered by all methods, the classification of the colleges in which most of the applicants licensed obtained their medical training, and the number of candidates licensed through reciprocity. Table M gives the standards of preliminary education that have been adopted by the different states, and the dates when the higher requirements are effective. Table N shows the remarkable progress that has been made in state board requirements during the last fourteen years. In brief, these statistics call attention to the kind of protection the people of each state have against incompetent or ill trained physicians.

FACTS REGARDING EACH COLLEGE

The statistics also give valuable information regarding medical colleges. Tables A and B show in what states graduates of each college were examined, and the results of the examinations. The results for several colleges would seem to indicate fair teaching methods, but this misconception is prevented by a knowledge of the facts set forth in Table D, which may show that the graduates of these colleges are refused examination by all but a few lenient states. Table E shows the results of the examinations for the group of colleges located in each state. Table F gives data regarding the colleges having fifty or more graduates examined during the year, and allows of comparison between colleges of nearly equal size. These statistics throw an important side-light on the facts regarding medical colleges which are published in August each year in the Educational Number of The Journal.

TOTAL REGISTRATION IN ALL STATES

These statistics show the number of candidates coming not only from each medical school in this country and Canada, but also coming from Europe and abroad. An accurate record is given of the number, the source and the character of the medical training of those who are entering the practice of medicine each year in this country. Altogether, by examination and by reciprocity, 5,423 physicians were licensed in this country during 1917 — thirty-eight less than in 1916. Of these, 3,369, or 62.1 per cent., were graduates of Class A medical colleges; 988, or 18.2 per cent., were from Class B; 297, or 5.3 per cent., were graduates of Class C medical colleges, and 769, or 14.4 per cent., graduated prior to 1907, when the first classification of medical colleges was prepared.

INFLUENCE OF THESE STATISTICS

Excellent systems of record keeping are now in use by state boards in many states where formerly no records whatever were kept, or where the systems were far from perfect. This publication of accurate data each year has indicated other directions in which improvements were needed, and many advances have been made in medical licensure, as indicated in Table N. The statistics also have aided largely in the improvement of medical education. Before the publication of these statistics, medical faculties did not know how frequently their graduates failed at the state license examinations, and that knowledge has led to important developments in the colleges, particularly in the securing of better equipment and better teachers and in the adoption of better teaching methods.

COOPERATION MUTUALLY ADVANTAGEOUS

The collection and publication of these statistics were begun by The Journal in 1903; since 1905 that work has been continued and developed as one of the functions of the Council on Medical Education. During all these years the work has had the hearty support and cooperation of the secretaries of the various state licensing boards, who have furnished reports of their examinations. Every report received has been carefully checked with alumni lists furnished us by the medical colleges. By this cross-checking, errors are avoided, and when discovered the state boards are notified. Thus, not only are state records corrected, but also these statistics are made accurate and reliable. We express our acknowledgments for the splendid cooperation of both the state licensing boards and the medical colleges by which the publication of these statistics has been made possible.

THE BÁRÁNY TESTS IN THE EXAMINATION OF AVIATORS

Our readers are no doubt aware that up to this time great emphasis has been placed on the Bárány equilibrium tests in connection with the examination of aviators. Already, however, there seems to be developing a reaction against assigning too great importance to these tests.

As Fridenberg[1] recently said: "It has been generally assumed that a normal labyrinth is the sine qua non and the only essential for equilibration." As he points out also, while nothing has been said about vision in its relation to flying, the questions of hypersensitiveness to bright light, the sureness of the sense of motion, the acuity of vision in lowered illumination, the appreciation of contrast in form, color and light, a rapid and accurate judgment of distance, direction and size and depending on all of these, pace, are an "interesting and practical problem." A further evidence is the finding of Assistant Surgeons Parsons and Segar[2] of the U. S. Navy, that in many cases the best ratings as aviators were obtained by men who had made the best showing under the Bárány tests.

Surgeon H. Graeme Anderson,[3] attached to the Royal Navy Service and as an adviser to the special medical administrative committee recently constituted by Great Britain, in an address before the Medical Society of London last month, presented the subject from every point of view based on his extensive experience. He corroborates the changing attitude toward the equilibration tests. "It has been assumed," he says, "that sound equilibration and muscle sense is essential to flying, so that the aviator would be conscious of his position in space, realize at once any deviations therefrom and correct these quickly. But in fog it has been found almost impossible to detect any deviation during flight. Time and again aviators coming out of the dark clouds or fog have found themselves flying one wing down, and it has been recorded that some have flown upside down without knowing it. Thus it is obvious that most of the impressions which control balance in flying come through the eyes." In fact, Surgeon Anderson, as an experiment, had himself blindfolded and his ears plugged with a telephonic connection to the pilot. The latter performed certain evolutions and Surgeon Anderson attempted to describe the position in space at various times. He was able to do this during the climbing and flying with right wing down and with the first spiral downward to the right. After that he was all at sea and thought the plane was climbing up continuously when in reality it was spiraling down to the left. He believes that this experiment goes far to prove that the aviator is for the most part dependent on impressions conveyed through the eyes for his sense of balance. He would not discard the equilibration, muscle sense and vestibular reactions, however, until further investigation has confirmed these points.

ACETYLSALICYLIC ACID, OR "WHAT'S IN A NAME?"

Under the caption "What's In a Name?" the current (April) issue of the *Journal of Industrial and Engineering Chemistry* has an editorial dealing with the nomenclatures—common and proprietary—of acetylsalicylic acid. The editorial was prompted by an article by Dr. Leech printed in the same issue. Replying to its own question:

> "The answer to this question in so far as it applies to acetylsalicylic acid (popularly known as aspirin) is the difference between eighty-eight cents, the price the druggist must pay for every one hundred tablets of Bayer aspirin, and forty cents, the cost of an equally pure American product. Naturally, this difference in cost is passed on to the individual consumer.
>
> "That no scientific justification exists for this difference in cost is clearly shown in the contribution by Dr. Paul Nicholas Leech, of the Chemical Laboratory of the American Medical Association, page 288 of this issue.
>
> "On the other hand, the excess profit fully warrants the extensive and shrewdly-worded advertising campaign now in progress, a campaign which must eventually fail, because in the first place, it is contrary to the prevailing spirit of modern advertising, the motive of which is constructive rather than destructive, and, in the second place, it appeals merely to the temporary ignorance of the public at large, and has no basis in fact.
>
> "We have been informed that the Custodian of Alien Enemy Property has taken charge of the stock interests of alien enemies in the company conducting this propaganda. Surely the Custodian will not care, even in a trustee capacity, to continue as a participant in a misleading campaign whose sole purpose is the perpetuation of a monopoly hitherto enjoyed under full patent protection."

The article to which the editorial refers is a somewhat technical one giving the findings of an examination made, at the request of the Council on Pharmacy and Chemistry, in the Chemical Laboratory of the American Medical Association by Paul Nicholas Leech, Ph.D., of various American brands of acetylsalicylic acid (aspirin). The result of the investigation may be summed up briefly in the statement that there are on the American market, made by American firms, several brands of acetylsalicylic acid that are just as good as, if not better than the Bayer product.

The Journal has called attention to the misleading propaganda on the part of the Bayer Company (Farbenfabriken vorm. Friedr. Bayer & Co.), in its attempt to perpetuate the monopoly granted under our inequitable patent laws. This is done by conveying the inference that the only pure acetylsalicylic acid on the market is that known as "Aspirin-Bayer." Physicians should again be reminded of the facts in the case of aspirin: Practically no other country in the world, and certainly not Germany, the original home of aspirin, would grant a patent either on acetylsalicylic acid, itself, or the process for making it. The United States granted both! As a result no one in this country except the Bayer Company could for seventeen years manufacture or sell acetylsalicylic acid either under its chemical name or under any other name. Nor was it permissible for hospitals or individuals to import it. While the monopoly held, the American people were compelled to pay from six to ten times as much for acetylsalicylic acid as were the people of Great Britain, France, Germany, Austria-Hungary, Denmark, Holland, Norway or Sweden. At a time when American druggists were compelled to pay 43 cents an ounce for acetylsalicylic acid as aspirin, just across the border in Canada it sold for about one-third the price.

About a year ago the Council on Pharmacy and Chemistry announced that "Aspirin-Bayer" had been deleted from New and Nonofficial Remedies while the scientific term, acetylsalicylic acid, was retained along with standards to insure its quality. The necessity for a standard becomes evident when it is remembered that acetylsalicylic acid is not yet an official drug, and its purity, therefore, is not subject to the control of the federal Food and Drugs Act. It is worth while at this time to remind physicians that several brands of acetylsalicylic acid (aspirin) have been found to comply with the standards set by the Council on Pharmacy and Chemistry and have been admitted to New and Nonofficial Remedies.[1] These, of course, are thereby subject to the control of the federal law to conform to the standard to which they profess.

Leech's report gives still greater weight to the suggestion that has been made for some time, viz., that physicians should prescribe acetylsalicylic acid under its scientific name rather than its proprietary name, even though, in the opinion of The Journal, the proprietary name, aspirin, has become common property since the expiration of the acetylsalicylic acid patent. Every consideration of public interest, of patriotism and of ordinary common sense should prompt physicians to specify acetylsalicylic acid in writing prescriptions.

Tuberculosis in Asia.—Tuberculous affections are much more active in Siberia than in Central Asia, though much less than in European Russia. The disappearance of the native tribes, the Buriats, the Yakuts, the Tunguses and others, which is rapidly being brought about by many social, political and other causes, is hastened by tuberculous disease among them.—Frank G. Clemou, The Geography of Disease, p. 456.

Current Comment

A CALL FOR FIVE THOUSAND MORE MEDICAL OFFICERS

If there is any one lesson that this war has taught the world it is that of preparedness. If it were not that it stands for a principle which is axiomatic, the reiteration of the word "preparedness" would become monotonous. As it is, the tremendous importance of the principle undoubtedly has prompted the appeal of the Surgeon-General, which appears on another page, for five thousand more volunteers for the Medical Reserve Corps. At present there are approximately 18,300 members in the Corps and in addition, about 1,500 men have been offered commissions who have not yet accepted. Thus there is a sufficient number for present needs and for the immediate future. But it is the ultimate future — it is what may develop in four, in eight, in twelve, in eighteen months for which preparations must be made. It will be noticed that the Surgeon-General calls for five thousand more volunteers for the Medical Reserve Corps NOW. The call is made on the organized profession. It is up to us, to the medical profession of the United States, to respond to this call—the call of our government, of our country. The Association is preparing, and has about ready for publication, a survey of the response the medical profession has already made. This survey will show in what states, in what counties and in what communities the profession has shown its patriotism and its self-sacrificing spirit in responding, and in which communities it has lagged behind. THE ORGANIZED PROFESSION WILL RESPOND TO THE CALL OF THE SURGEON-GENERAL! So far as possible the response must be made with the consideration of the actual needs of the public — not as expressed by the individual physician himself, but by the profession as a whole in his community, county and state. Preparations are already in the making for conducting the "drive" for this new increment of five thousand physicians. Let every reader ask himself the question: Is it my duty to volunteer? And then let him answer it honestly!

THE PHYSICIAN AND THE AVIATION SERVICE

It has been appreciated both here and abroad that the aviator is a peculiar type — a "strange bird," as it were. It is therefore especially interesting to follow the development of the regulations concerning the physical examination of aviators and to study the large experience of our allies; this experience has apparently modified the point of view regarding the physical qualities associated with special aptitude for flying. That the great importance of this matter has been recognized in Great Britain is shown by the appointment of a special medical service for the air forces. The character of the men selected for this division of the British military services is a further recognition of the special consideration to be given to this subject.[1] The British Air Medical Service has had placed at its disposal special wards in naval and military hospitals in order to study the physiology and pathology of aviators. All of the medical arrangements of the air forces are to be centralized under its direction. Our man power has not been picked and repicked and selected to such an extent as has that of our allies. Our universities and colleges and athletic organizations contain thousands of men of the type specified as particularly adapted for aviation. In the first sorting of this material the experience of the European nations should be utilized so that in the future we shall not have to retrace our steps to make good unnecessary losses.

ENTRANCE CONDITIONS IN MEDICAL SCHOOLS

One of the problems which has lately come uppermost in dealing with medical schools is that relating to entrance conditions. The various phases of this problem are discussed in an article by Dr. Harley E. French[2] published in this issue of The Journal. Two state licensing boards recently have adopted rules absolutely prohibiting the admission of students with conditions. This rule is an extreme reaction against the practice in former years of a considerable number of medical colleges — and of a much smaller number at present — of admitting students with an overabundance of conditions. To adopt so extreme a measure, however, in an effort to regulate a few medical colleges which are unwilling voluntarily to enforce reasonable entrance requirements, would seriously interfere with the administration of requirements for admission in a large majority of the medical schools which are conscientiously enforcing them. As with any other regulation applying to medical schools, the rule relating to conditions should not be so rigid as to prevent the entrance examiners of our high grade medical schools — who, after all, are the highest authorities on this question — from dealing wisely with each individual student who applies for admission. As a matter of fact, certain students may meet the technical requirements of the rule who are not mentally qualified to take up the study of medicine. These would be accepted by the low-standard colleges, but would be rejected by the examiners of our leading medical schools. On the other hand, in the experience of medical deans, there are many students who have had more than the minimum amount of training required, who are mature and, in fact, are fully equipped mentally to enter on the study of medicine but who lack a portion of the technical requirements specified in the rule. The latter, with conditions, will undoubtedly make better medical students than the former without conditions. Meanwhile, the decision as to whether conditions are to be allowed or not is necessarily a part of the problem of administering entrance requirements and should be left to those who are expert in that work. Given an experienced and intelligent entrance examiner — an essential of every approved educational institution — and he should be left free to administer the details of entrance qualifications, even to the allowing of conditions where that appears to be justified. Should the privilege be abused, the fact would soon be discovered by standardizing agencies, which could then withdraw their approval from the college until such abuses were corrected. All rules governing medical education which are worth while have emanated from the better grade of our teaching institutions. Any rule, therefore — including the rule in regard to conditions — which would prevent such action as our leading educational institutions may find desirable, would prevent the further development of educational ideals and methods.

---

[1] The staff consists of the Director-General, Navy Medical Service, as chairman; the Director-General, Army Medical Service; a medical administrator of the air force; Flying Surgeon R. C. Munday, R. N., who receives the rank of Surgeon-General; an assistant medical administrator, Major C. B. Heald, who becomes lieutenant-colonel; a neurologist, Dr. Henry Head, F.R.S.; a physician, Surgeon-General H. D. Rolleston, R. N.; a surgeon, Capt. Raymond Johnson, R. A. M. C.; a physiologist, Dr. Leonard Hill; and Sir Walter Fletcher, F.R.S., secretary of the Medical Research Committee. Most of these men have already had some experience in connection with the medical work of the Royal Flying Corps. It is expected that temporary air force commissions will be granted to others, including Major J. L. Burley, Major H. C. T. Langdon and Surgeon H. Graeme Anderson, R. N., and Major Martin Flack, who have had special experience in this work.

RECIPROCITY IN MEDICAL LICENSURE

Thirty-nine states have established reciprocal relations with seven or more other states by which the license to practice medicine is accepted in lieu of a second written examination. Generally speaking, the methods by which such reciprocal relations are being administered at the present time tend toward the lowering of educational standards. There appear to be three distinct provisions under which such relationships are established. A few states take the ground that under the reciprocal agreements they must accept all candidates who apply for registration holding licenses from the other states. Under the widely differing standards held by the various boards, such an agreement would leave a wide open door whereby poorly educated physicians as well as others could secure a license in any of the states included under such an agreement, and the lowest educational standard enforced by any of the states would be the highest standard which could be effective. To limit the relationships to only a few states merely decreases the evil, since even the best regulated state board will occasionally register candidates who may not in all respects meet the requirements of some of the other reciprocating states. Furthermore, to limit reciprocal relationships to only a few states is to deprive the physicians of the state of the wider privileges which they should have through interstate reciprocity. Another basis for reciprocity, adopted by a larger number of states, provides that the license of the other state be accepted in lieu of the written examination only, and that the applicant must meet the educational and moral requirements of the state which accepts him under the reciprocal arrangement. In other words, each board retains the right to use its discretion in the acceptance of any candidate for registration under reciprocity. This plan is superior to the first one mentioned, in that it enables each board not only to establish relationships with a larger number of states, but also to uphold its educational standards for every applicant registered. Unfortunately, a few states, even with this arrangement, are not administering its provisions as strictly as might be desired. The third plan is that under which any well qualified physician who has been licensed in any state will be accepted no matter whether that state reciprocates or not. Eight states[1] have now adopted this plan and the number should be increased. It is the best provision for all parties concerned. The well qualified physician who desires to move from one state to another is not prevented from so doing through the lack of legal provision for reciprocal relations or through the arbitrary refusal of a licensing board to provide for such relationships; the state law is upheld since the board accepting such candidates lays strong emphasis on the moral and educational qualifications of the physician and, finally, this plan upholds the best interests of the public since only well qualified physicians may care for the sick and injured in the states which thus accept them.

DANGERS FROM CHLORIN SHORTAGE

A situation full of peril for many cities in this country has recently developed as a result of the interference with normal railway transportation due to war emergencies.[2] Several hundred cities and towns have become dependent on chlorin treatment for safeguarding their public water supplies. Even a temporary interruption of chlorination has been followed with disastrous results. We have called attention to several instances, notably in Milwaukee, Wis., and Quincy, Ill., in which stopping of chlorin treatment has led to serious outbreaks of water borne typhoid. It now appears that inability to obtain liquid chlorin as a sterilizing agent is becoming widespread. With singular lack of foresight a general order on February 1, designed to give some relief in the shipping of liquid chlorin from the manufacturing plants to the waterworks, failed to specify the return of the empty cylinders. In consequence it is said that empty cylinders are accumulating in railroad freight houses, in filtration plants and in scores of isolated places all over the country. As a result the manufacturers' reserve of empty cylinders is practically exhausted. A number of municipalities appear to have been on the verge of serious trouble from this cause. Shipments have been sent by express, chlorin has been borrowed from local chemical plants, and waterworks managers have resorted to a variety of emergency methods. The danger from cessation of chlorin treatment is all the more serious, because many cities have come to rely on this method for the treatment of rather badly polluted waters and have no other means of safeguarding the quality. During the years the chlorin treatment has been in use, the pollution of some of these supplies has certainly not lessened, so that any interruption of the treatment may be fraught with exceedingly serious consequences. The situation deserves immediate attention at Washington.

---

[1] These states are Arizona, California, Colorado, Delaware, Maryland, New Hampshire, New Jersey and North Carolina.

Medical Mobilization and the War

A CALL TO THE AMERICAN MEDICAL ASSOCIATION

WAR DEPARTMENT
OFFICE OF THE SURGEON-GENERAL
WASHINGTON

From: The Surgeon-General.
To: American Medical Association.
Subject: Medical Reserve Corps.

April 3, 1918.

1. A memorandum of plan has recently been submitted to the Secretary of the American Medical Association for the utilization of the organization and machinery of the Association, in addition to the activities of the other bodies, viz., the Medical Section of the Council of National Defense and the different sections and organizations of the American Medical Association for the purpose of securing future increment to the Medical Reserve Corps and for keeping the numerical strength of the Corps up to the requiments of the service.

2. This plan contemplates a close cooperation between the office of the Surgeon-General and the officials of the American Medical Association, through the officials of the different state and county medical societies and through the different section organizations of the American Medical Association.

3. The present needs of the service will require all of the officers of the Medical Reserve Corps who have received their commissions and who are ready for active service. The additional increase in the Army during the next few months will probably necessitate the service of 5,000 physicians who as yet have not made application for a commission in the Medical Reserve Corps.

4. Under the present authorization for the Army it is estimated that the Medical Reserve Corps will need a steady increase of at least 2,500 applicants a year during the continuance of the war, for the purpose of replacements due to casualties, resignations and discharges, and to provide a medical personnel for organizations not at this time authorized. Under the present arrangement the Surgeon-General is authorized to maintain a strength of 3,600 medical officers in the training camp for medical officers for the purpose of instruction.

5. It is earnestly desired that the interests of the civil communities be conserved as far as possible and that no enlistments in the Medical Reserve Corps be made that would work serious hardship upon any community, manufacturing concern or other civil activity by taking from such community, manufacturing concern or other civil activity, physicians whose services are needed for the efficient and competent care of the civil population or the employees of large concerns.

6. To this end the department desires the closest cooperation and assistance of the American Medical Association, its officers and its allied organizations, believing that through its organizations the additional increment to the Medical Reserve Corps can be most satisfactorily obtained and the necessary increment for replacements be secured without in any way depriving any community of physicians whose services are necessary to its welfare and without depriving any manufacturing or other concern of its medical personnel when such personnel cannot be spared.

7. It is believed that by working through the Association and the subordinate bodies of the state and county medical societies, the best possible results can be obtained and the needs of the service can be supplied with competent and efficient professional men to meet not only the present necessities of the service, but to supply its future needs in the way of officers for the Medical Reserve Corps.*

8. In making request of the American Medical Association for its cooperation in this great work, I am appreciative of the very valuable assistance which has been rendered the department by the Association in the past and feel well assured that with the cooperation of the American Medical Association the department will in no way be handicapped for lack of competent, efficient medical officers for its Reserve Corps.

W. C. GORGAS, Surgeon-General, U. S. Army.

Officers Needed for Regular Medical Corps

There are at present approximately 650 vacancies in the regular Medical Corps of the Army, and examinations are being held throughout the country on the first Monday of each month to secure men for these positions. Full information concerning the examination may be procured on application to the Surgeon-General, Washington, D. C. The qualifications have been given many times in THE JOURNAL, but in order to save unnecessary correspondence the following essential qualifications are repeated:

QUALIFICATIONS

The applicant must be a citizen of the United States between 22 and 32 years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, of good moral character and habits, and shall have had at least one year's postgraduate hospital internship. There are numerous attractions to this service as a career; the greatest inducement, however, at this time is the country's great need for men to fill these vacancies.

Personnel of the Medical Department

For the week ending April 5, 1918, the personnel of the Medical Department of the Army included:

MEDICAL CORPS: 838, including 1 major-general, 66 colonels, 102 lieutenant-colonels, 175 majors, 2 captains and 492 lieutenants.

MEDICAL RESERVE CORPS: 18,279, including 1,135 majors, 4,310 captains and 12,834 lieutenants. On active duty: *15,388, including* 1,036 *majors*, 3,801 captains and 10,551 lieutenants.

MEDICAL CORPS, NATIONAL GUARD: 1,212, including 16 lieutenant-colonels, 251 majors, 151 captains and 794 lieutenants.

MEDICAL CORPS, NATIONAL ARMY: *100, including 3 brigadier-generals*, 11 *colonels, 78* lieutenant-colonels and 8 majors.

DENTAL CORPS, 209; DENTAL RESERVE CORPS, 5,182, *of* whom 1,358 are on active duty; DENTAL CORPS, N. G., 259; VETERINARY CORPS, 18; VETERINARY RESERVE CORPS, 1,428, *of* whom *784* are on active duty; VETERINARY CORPS, N. G., 53; VETERINARY CORPS, N. A., 347; SANITARY CORPS, 1,032, and AMBULANCE SERVICE, 151, constitute the *remainder* of the commissioned personnal.

The DISCHARGES in all branches of the service to date are:

Causes	Number MRC	MC,NG	DC,NG	San. C.
Physical disability	502	36	6	4
Inaptitude	190	14	0	1
Other branches of the service	428	9	2	41
Domestic troubles	50	1	0	1
Resignations	143	44	5	8
Needed by the community	35	1	0	0
Deaths	43	3	0	0
Dismissals	3	2	0	0
	1,394	110	13	55

---

* NOTE.—An application blank and a list of the examining boards will be sent by THE JOURNAL on request.

Medical Military Legislation

The House Committee on Military Affairs has favorably reported the bill (S. 3863), which passed the Senate, to provide quarters or commutation thereof to commissioned officers in certain cases.

Medical Officers Wounded in Action

The following medical officers from Pennsylvania are reported as recently wounded in action: Lieut. John B. Nutt, formerly an intern of the University of Pennsylvania Hospital and a practitioner of Williamsport, Pa.; and Capt. Edward B. Hodge and Lieut. Henry K. Diller with the Pennsylvania Base Hospital Unit No. 10, which is under British command.

Transportation of Wounded Soldiers

According to the *Army and Navy Register*, the question of hospital ships in connection with the return of wounded soldiers from abroad has been settled, and the Navy Department has taken charge of the transportation on returning transports. The transports will not be fitted out as hospital ships, but the sick bay is to be increased. The *Army and Navy Register* states that there has been suggested a possible objection to using transports in that they do not have the protection of the Geneva cross and that General Gorgas realizes that there will be a great deal of criticism if one of these transports, loaded with sick and wounded, is sunk. It states, however, that he believes the large transports should be made use of for comfort and real safety, as it is now well known that the Germans do not recognize any hospital ship flags.

Hospitals for Reconstruction of Disabled Soldiers

It is announced that the following hospitals will be used in beginning the work of physical reconstruction: General Hospital No. 2, Fort McHenry, Md.; General Hospital No. 3, Colonia, N. J.; General Hospital No. 4, Fort Porter, N. Y.; General Hospital No. 6, Fort McPherson, Ga.; General Hospital No. 7, Roland Park, Baltimore; General Hospital No. 9, Lakewod, N. J.; General Hospital No. 13, Dansville, N. Y.; General Hospital No. 14, Fort Oglethorpe, Ga.; Army and Navy General Hospital, Hot Springs, Ark.; Walter Reed General Hospital, Takoma Park, Washington, D. C.; Letterman General Hospital, San Francisco; Base Hospital at Fort Des Moines, Iowa; Base Hospital at Fort Riley, Kan.; Base Hospital at Fort Sam Houston, Texas.

The hospital at Fort McHenry is now being constructed, and work is under way connecting several structures with large wooden corridors about 15 feet in width. The administration building is a modern two story stone structure at present occupied by the staff of Major Purnell, commanding officer. A Red Cross house, under the direction of the Baltimore chapter of the Red Cross is also being built at this point. This building will be in the shape of a Greek cross, and the site selected is a high point overlooking the bay. It will contain a sun parlor, diet kitchen, reception room, library, large assembly room and other accommodations for convalescent soldiers. Major Wilson Henderson is in charge of the rehabilitation work at the reconstruction hospital.

It is understood that insane patients will be cared for at General Hospital No. 4, Fort Porter, N. Y.; the blind and deaf at General Hospital No. 7, Roland Park, Baltimore, Md.; epileptics and neurotics at General Hospital No. 13, Dansville, N. Y.; and special provisions made for amputation work at Walter Reed and Letterman Hospitals.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending March 29, 1918

1. ANNUAL ADMISSION RATE PER 1,000 (DISEASE ONLY):
All Troops
National Guard Camps 1,522.0
National Army Camps 1,103.5
Regular Army 1,814.7
1,513.8
2. NONEFFECTIVE RATE PER 1,000 ON DAY OF REPORT:
All Troops
National Guard Camps 49.4
39.1
National Army Camps 58.7
Regular Army 44.4
3. ANNUAL DEATH RATE PER 1,000 (DISEASE ONLY):
All Troops 9.8
National Guard Camps 3.6
National Army Camps 14.0
Regular Army 10.1

NEW CASES OF SPECIAL DISEASES REPORTED DURING THE WEEK ENDING MARCH 29, 1918

NEWS OF THE CANTONMENTS

Thirty-First Division, Camp Wheeler, Macon, Ga.

April 5, 1918.

PERSONAL

Major R. C. Turck has been promoted to lieutenant-colonel and transferred to Camp Doniphan, Fort Sill, Okla., where he will be division surgeon of the Thirty-Fifth Division, National Guard. The news reached him while sick in the base hospital, and was cheering to him as well as pleasant to his many friends, who were nevertheless sorry to see him leave the Thirty-First Division.——Major Job Patterson has returned from Camp Merritt.——Major Rugh of the orthopedic branch of the S. G. O., is organizing the orthopedic work, which had not heretofore been done.——Major O'Connel has returned from a visit to his family, where five of his children were sick.——A lieutenant of one of the regiments is about to be tried for making charges to enlisted men for administering salvarsan and other drugs.——A dental surgeon was recently tried and convicted of charging enlisted men for dental work.

SURVEYS

Major Arthur S. Pendleton expects to begin a second neurological survey of the troops soon. It is hoped that the frequent and various surveys with their resulting eliminations, will not reduce the division to zero, but one sometimes sees the vanishing point in the distance.

Another board on food conservation has arrived. Boards on various subjects continue to arrive and depart. It is presumed that they accomplish some useful purpose; but in some cases the effect is difficult to detect.

BASE HOSPITALS

There are now 679 patients in the base hospital and a total sick of but 688 in the division. There are now but eighteen cases of mumps, two of measles, one meningitis, no scarlet fever and 105 remaining cases of pneumonia. Most of the pneumonias are old convalescent cases. The sick rate is now down to 3.7 per cent., which is below the average in all camps.

INSPECTION

Lieutenant-Colonel McCormack, M. C., is expected to arrive soon for inspection of the sanitary train. Although the sanitary train is one of the most important organizations in the division, yet in six months it has never been inspected by any officer outside the division. Much benefit is expected from Colonel McCormack's visit.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

April 8, 1918.

The system of regimental guards over sick prisoners at the base hospital has been discontinued. The camp adjutant daily details a guard consisting of six privates, a sergeant and a corporal, who report at 4 o'clock each afternoon to Lieut.-Col. Will L. Pyles at the hospital. They will be used to guard prisoners sick in the wards and will be rationed and quartered at the institution during the twenty-four hours they are on duty.

COLONEL ALLEN EXONERATED

"Not guilty" was the finding of the general court martial that tried Lieut.-Col. John H. Allen, medical officer of Camp Zachary Taylor, charged with negligence in the death of Private Otha Murray of Cumberland County, and also charged with showing disrespect toward his commanding officer. The findings of the court martial were approved by the reviewing authorities and Colonel Allen is permitted to continue in the same capacity at the local camp as he held before the charges were brought against him.

The court convened on March 5, at which time Colonel Allen and several other officers of the Medical Corps were called to the witness stand. The charges against Colonel Allen stated that he acted without the proper investigation and regard for the health of Private Otha Murray in recommending his discharge from the base hospital. During the trial attempts were made by the prosecution to prove that the accused had not investigated the case of Otha Murray and had, without taking steps to learn the man's condition, asked for his release from the base hospital. No condemning evidence was brought out against the colonel on these grounds.

Eighty-Sixth Division, Camp Grant, Rockford, Ill.

April 6, 1918.

The sick rate at this camp is probably the lowest of any National Army camp in the country. The noneffective rate was 2.61 and the annual admission rate was 704 per thousand.

Major McKinney has gone East on a short trip and Captain Hutchings is taking his place as sanitary inspector pro tem.

QUARANTINE

Patients with mumps are not quarantined in this camp, although those suffering from other contagious diseases are being quarantined. The quarantine is maintained by Company Guard: that is, an armed sentry is placed at every entrance, preventing any one but authorized officers from entering or leaving the building. However, the company may, and should be, taken out for drill as a unit, but must not be mixed up with any other organization at drill or at any other time. Members of the company are not permitted to attend any public entertainment.

ORTHOPEDIC UNIT

An orthopedic unit for field work has been established in one of the buildings of the Depot Brigade in charge of Lieutenant McCormack. The unit was established by Major Peters, visiting orthopedist from the Surgeon-General's Office, and it is just beginning operation. The main object is to examine and care for deficient feet by means of proper exercises under the guidance of competent orthopedists. A chiropodist is attached to the unit.

CORRECTION

Under "Orders to Officers of the Medical Reserve Corps," issue of March 23, appears this order: *Honorably discharged* on account of physical disability existing prior to his entrance into the service, Lieut. CARL R. DOTEN, Providence, R. I. This order should read: *Honorably discharged* on account of physical disability incident to the service.

ORDERS TO OFFICERS OF THE MEDICAL CORPS AND OF THE MEDICAL CORPS OF THE NATIONAL ARMY

To Camp Cody, Deming, N. M., base hospital, from San Francisco, Major JOHN B. ANDERSON. *For duty, from Fort Snelling*, Capt. HARRY J. O'BRYAN.

To Camp Crane, Allentown, Pa., for inspection, and on completion *to his proper station*, Col. EDWARD L. MUNSON. *For duty, from* Camp Doniphan, Lieut.-Col. WILLIAM T. DAVIDSON; *from* Camp Upton, Lieut. HARVEY E. WEBB.

To Camp Dix, Wrightstown, N. J., *Camp Merritt, N. J., Camp Upton*, Long Island, N. Y., *Lakewood, N. J.*, for duty, and on completion *to his proper station*, Col. FREDERICK F. RUSSELL. *To Camp Dix*, base hospital, from San Francisco, Major ROBERT H. WILDS.

To Camp Dodge, Des Moines, Ia., base hospital, from San Francisco, Major FLETCHER C. McFARLAND.

To Camp Forrest, Chickamauga Park, Ga., for duty, from Camp Wheeler, Lieut. ALBERT E. PAGAN.

To Camp Fremont, Palo Alto, Calif., base hospital, from Camp Fremont, Major RAY W. BRYAN.

To Camp Greene, Charlotte, N. C., base hospital, from Camp Greene, Lieut. LEON H. CORNWALL.

To Camp Lee, Petersburg, Va., base hospital, from Camp Sherman, Major ALEXANDER W. WILLIAMS.

To Camp Lewis, American Lake, Wash., base hospital, from San Francisco, Lieut.-Col. WILLIAM R. DAVIS.

To Camp Logan, Houston, Tex., *Camp MarArthur*, Waco, Tex., *Camp Bowie*, Fort Worth, Tex., for consultation, and on completion *to his proper station*, from Camp Beauregard, Lieut.-Col. GEORGE F. LULL. *To Camp Logan*, base hospital, from Camp Logan, Lieut. ALBERT AISENSTADT.

To Fort MacArthur, Calif., for physical examination to determine his fitness for active duty, and on completion *to his home*, Capt. CLARENCE E. LAUDERDALE.

To Camp Meade, Annapolis Junction, Md., base hospital, from Surgeon-General's Office, Lieut.-Col. HOWARD H. JOHNSON. As orthopedic surgeon, from Camp Devens, Lieut. EDWARD B. MACON.

To Camp Sevier, Greenville, S. C., base hospital, from Fort Myer, Major JULIAN M. CABELL.

To Camp Sherman, Chillicothe, Ohio, base hospital, from Camp Sherman, Lieut.-Col. EDWARD G. HUBER.

To Camp Upton, Long Island, N. Y., base hospital, from Army Medical School, Lieut. CALVIN H. GODDARD.

To Camp Wadsworth, Spartanburg, S. C., for duty, from Camp Jackson, Major JAMES D. JOHNSTON.

To Camp Zachary Taylor, Louisville, Ky., base hospital, from Fort Riley, Major LEONARD S. HUGHES.

To Corpus Christi, Tex., for special inspection and on completion *to his proper station*, Col. WILLIAM F. LEWIS.

To Fort Des Moines, Ia., base hospital, from Camp Sherman, Major LEOPOLD MITCHELL.

To Fort Ethan Allen, Vt., base hospital, from Camp Beauregard, Lieut.-Col. GEORGE F. LULL; from Fort Oglethorpe, Major WILLIAM B. ALLEN.

To Fort Jay, N. Y., for temporary duty, from Camp Upton, Lieut. FREDERICK E. HERPEL.

To Fort McHenry, Md., base hospital, from Fort Oglethorpe, Major WILLIAM D. HERBERT.

To Fort Oglethorpe for instruction, from Camp Beauregard, Major HOMER SCOTT.

To Fort Riley for duty, from Camp Crane, Major CHARLES L. GANDY; from Fort Riley, Major ROBERT H. DUENNER.

To Laurel, Md., for inspection; and on completion *to his proper station,* Col. PERCY M. ASHBURN.

To New Orleans, La., Charity Hospital, for instruction, and on completion *to their proper stations,* from Camp Sevier, Majors ALEX. M. BRAILSFORD, JR., LARKIN SMITH; Lieuts. WILLIAM R. CROSS, JAMES H. S. MORISON.

To New York City for duty, and on completion *to his proper station,* Col. ROBERT E. NOBLE. For instructions, from Panama Canal Department, Lieut. DAVID N. W. GRANT.

To report in person to the commanding general, Western Department for duty, Lieut.-Col. EDWIN W. RICH; Major EUGENE L. SWIFT.

To Rochester, Minn., Mayo Clinic, as assistant director of course in war surgery and fractures, Major JAMES C. MASSON.

To Washington, D. C., for temporary duty in the Surgeon-General's Office, from Hoboken, Major HARRY N. KERNS.

Resignations of Major VAN BURAN KNOTT, and Lieut. CHARLES E. SCHWARTZ, accepted.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Camp Gordon, Atlanta, Ga., base hospital, Lieut. ROBERT C. BLACK, Birmingham.

To Camp Hancock, Augusta, Ga., for duty, from Camp Hancock, Capt. MACK ROGERS, Birmingham.

To Camp Jackson, Columbia, S. C., to examine the command for mental and nervous diseases, from Philadelphia, Lieut. TOOMBS LAWRENCE, Tuscaloosa.

To Camp Lee, Petersburg, Va., for duty, from Fort Oglethorpe, Lieut. BENJAMIN L. LEWIS, Samson.

[illegible] r instruction, Lieut. WILLIAM R. K. BECK, [illegible] Oglethorpe, Lieut. HENRY C. HARRIS, [illegible]

[illegible] AUGUSTUS D. MATTHEWS, Ariton, and [illegible] GE, Muscle Shoals, accepted.

Arizona

To Fort Riley for instruction, Lieut. LAWRENCE D. DUSCH, Superior.

Arkansas

To Canal Zone, Panama, Canal Department, for duty, from Fort Oglethorpe, Capt. DOWELL GANN, JR., Little Rock.

To Fort Riley for duty, from Fort Riley, Lieut. FOSTER JARRELL, Huttig. For instruction, Lieut. CHARLES G. HINKLE, Batesville.

To New Orleans, La., Charity Hospital, for instruction, and on completion *to his proper station,* from Camp Sevier, Lieut. ARTHUR C. HANEY, Atkins.

To Camp Gordon, Atlanta, Ga., to examine the command for mental and nervous diseases, from Camp Joseph E. Johnston, Lieut. WILLIAM J. FLEMING, Wauwatosa.

To Camp Upton, Long Island, N. Y., for duty, from Fort Riley, Capt. CONRAD W. WILKOWSKI, Chippewa Falls.

To Camp Wadsworth, Spartanburg, S. C., base hospital, Lieut. ERWIN G. LINKMAN, Milwaukee.

To Camp Zachary Taylor, Louisville, Ky., for duty, and on completion *to his proper station*, Major NELSON M. BLACK, Milwaukee.

To Chicago, Ill., Northwestern University Dental School, for inspection and instruction, and on completion *to Toledo, Ohio*, for inspection, and on completion *to his proper station*, Major ROBERT H. IVY, Milwaukee.

[illegible] *Kan.*, for duty, from Fort Riley, Lieut. [illegible], New Holstein.

[illegible], from Fort Riley, Lieuts. CHARLES M. [illegible] RUSSELL R. HEIM, Marinette. For instruction, Lieuts. WILLIAM F. BAKER, Birnamwood; PETER L. SCANLAN, Prairie du Chien; FRANCIS J. BROGHAMMER, Superior.

To Jefferson Barracks, Mo., for duty, Capt. NORMAN E. McBEATH, Livingston.

To Lakewood, N. J., for duty, from Ann Arbor, Capt. OSCAR C. WILHITE, Lake Geneva.

To New York City, Cornell Medical College, for instruction, in military roentgenology, from Fort Riley, Lieut. JOSEPH C. BAIRD, Eau Claire.

To Rockefeller Institute for instruction in laboratory work, and on completion *to Army Medical School* for duty, from Army Medical School, Lieut. HENRY F. HOESLEY, Shullsberg.

To San Francisco, Calif., for instruction, and on completion *to his proper station*, from Camp Cody, Lieut. CLARK O. DECKER, Crandon.

Honorably discharged on account of physical disability existing prior to entrance into the service, Lieuts. CLARK L. CAIN, Elmwood; DANA B. DISHMAKER, Kewaunee.

Wyoming

To Camp Dodge, Des Moines, Iowa, with the board to examine the troops for cardiovascular diseases, Lieut. DURWARD B. PARK, Laramie.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Upholding Venereal Disease Regulations.—An attempt at San Jose to obtain the release by habeas corpus proceedings of persons quarantined for venereal diseases under the regulations of the state board of health was prevented by Judge J. R. Welch in the superior court, who dismissed the case and remanded the infected persons to the care of the health officer. The regulations have been similarly upheld at San Diego and Los Angeles.

Personal.—Dr. Alice G. H. Anderson, Los Angeles, has been appointed head of the medical department of the woman's division of the state hospital, Patton, and assumed her new duties, April 1.——Dr. Frederick W. Rinkenberger has succeeded Dr. William H. Harrison at the Emergency Hospital, San Francisco, and Dr. Charles H. Peterson has been appointed to the position vacated by Dr. Joseph H. D. Roger.——Dr. La Verne C. Wright, Oakland, left March 30 for France, where she will do relief work among the refugees.——Dr. Wilfred H. Kellogg, director of the bureau of communicable diseases of the state board of health, was made secretary of the board to succeed Dr. Wilbur A. Sawyer, who has joined the colors.

FLORIDA

Drive for a New Hospital.—The campaign to raise funds to build the Good Samaritan Hospital, Palm Beach, closed March 11. Palm Beach has subscribed $32,000 and West Palm Beach, $12,000, to the fund of $60,000. As $25,000 had been raised last year, the fund was oversubscribed by $9,000.

Sanitation for Shipyards.—The state board of health has taken steps to place and keep the district surrounding the plant of the Pensacola Shipbuilding Company, in a thoroughly sanitary condition. The plan includes the installation of a sewage disposal system. The zone extends for a radius of three quarters of a mile about the plant.

Referendum for County Sanatorium.—The Florida Antituberculosis Association is planning a campaign to secure the establishment of a tuberculosis hospital for Duval County, and will, it is expected make this question an issue at the next general election in June. It is said that there is no public institution in the state for the treatment of tuberculosis.

GEORGIA

New Sanitary Officer.—W. C. Howard, Pensacola, Fla., has been made city health and sanitary officer of Albany.

Society Entertains Staff.—The members of the medical staff of the Atlanta and Fulton County Antituberculosis Society were entertained at dinner by the president and officers of the organization, March 26. During 1917, 1,336 patients were examined in the clinics maintained by the society, including 864 new patients, of whom 136 were children. The medical staff is now headed by Dr. George M. Niles.

ILLINOIS

Lake Forest Establishes Hospital in France.—A hospital has been established in St. Cloud near Paris, by a group of people of Lake Forest headed by Mr. and Mrs. Harold Bryant, for the use of American soldiers, with accommodations for twenty-five patients.

Personal.—Dr. George A. Lighte, Tallula, has been appointed resident medical officer for the Rock Island Military District.——Dr. Joseph P. Comegys, Rock Island, has been appointed federal physician for the examination of prisoners arrested in the sanitary zone around the Rock Island Arsenal.

To Promote Hospital Efficiency.—A joint meeting of the medical staffs of the hospitals of Peoria was held at St. Francis Hospital, March 18, in order to unify the work of the institutions and promote efficiency. At the meeting Dr. William Engelbach, St. Louis, gave an illustrated lecture on "Diseases of the Ductless Glands."

Epileptic Home Ready Next Month.—The state epileptic colony, Dixon, in the establishment of which $1,000,000 has been expended, will be ready to receive patients, May 1. The plant consists of seventeen buildings located on a plot of 1,100 acres on Rock River, above Dixon. Eventually 2,000 patients will be accommodated, but at first groups of fifty will be admitted. Dr. Henry B. Carriel, Jacksonville, is superintendent of the institution.

Chicago

Personal.—Dr. Frank W. Taussig, chairman of the United States Tariff Commission, has been placed at the head of the special committee to conduct an inquiry into the milling industry.

Expensive Expectoration.—March 21, 235 persons were arrested, charged with violating the city ordinance prohibiting expectoration on sidewalks and in public places. Of the accused 226 pleaded guilty, and were each fined $1.

Hospital Unit Leaves.—Base Hospital Unit No. 11, commanded by Major Nelson M. Percy, M. C., U. S. Army, and composed of 152 enlisted men and 100 nurses from St. Joseph's, St. Mary of Nazareth, and Augustana hospitals, left Chicago for Des Moines, Iowa, April 2.

Doane's Work in Washington.—Under the direction of Major Philip Schuyler Doane, M. R. C., U. S. Army, the Emergency Fleet Corporation in Washington is organizing a welfare service for its thousands of employees in that city and in the shipyards on the sea coast and the Great Lakes.

Writ Denied.—March 27, Judge Oscar M. Torrison entered an order overruling the motion of counsel for Drs. Arthur L. Blunt and Isaac Hodgens, for a writ of certiorari to compel the state board of registration and education to produce in court the records of the proceedings by which that body revoked the licenses of the two physicians.

MARYLAND

Personal.—Dr. Charley I. Hammond, Baltimore, was taken suddenly ill recently and rushed to Mercy Hospital where it was found that he was suffering from uremic poisoning. His condition is reported improved.——Dr. Frank J. Flannery, resident physician of Mount Hope Retreat, suffered a severe nervous shock and was badly shaken up in a collision between his automobile and a motor bus; he is reported as much improved.

Hospital Fund Raised.—The $10,000 emergency fund of the University of Maryland Base Hospital Unit No. 42 has been completed. Subscriptions amounting to $5,854.51 were received by Dr. James M. H. Rowland, dean of the University of Maryland, who is treasurer of the fund, and the executive committee of the Maryland branch of the Red Cross gave $5,000. This oversubscribes the amount. It is expected that orders to leave for the port of embarkation will be received within the next two weeks.

MISSISSIPPI

Personal.—Dr. Francis E. Harrington of the United States Public Health Service has succeeded Dr. J. A. Watkins in charge of the Mississippi cantonment work at Hattiesburg.——Dr. Matthew J. L. Hoye has been appointed superintendent of the East Mississippi Insane Hospital at Meridian, to succeed Dr. James M. Buchanan who served in that office for twenty-seven years.——Dr. Charles D. Mitchell, Pontotoc, has been appointed superintendent of the Mississippi Insane Hospital, Jackson, in place of Dr. Robert M. Butler, Liberty, resigned. He assumed his new duties, April 1.——Dr. W. E. Noblin, Yazoo City, has been appointed county health officer to succeed Dr. Orrin H. Swayze.

Miscellaneous.—Through Dr. Oscar Dowling of the Louisiana State Board of Health, Dr. Waller S. Leathers, University, executive officer of the state board of health, has made arrangements to take care of two lepers from Harrison County on the Mississippi Gulf Coast. They will be treated in the state institution.——An appropriation of $25,000 will be asked from the legislature for the building of a new hospital at Biloxi.——The reports of the committee on eleemosynary institutions on the charity hospital at Vicksburg and the state tuberculous sanatorium at Magee, which were submitted to the state department of health, show both institutions to be in good condition and well managed. Dr. Hicks of the charity hospital of Vicksburg asked for an appropriation of $18,000 for improvements. The committee reported that the support fund should be increased about 20 per cent. on account of the increased cost of food, and also recommended the transfer of the property to the state. The tuberculosis hospital had not been entirely completed at the time of the report and many recommendations for additional buildings and equipment were made.

NEW JERSEY

Personal.—Dr. Edward B. Rogers, Collingswood, captain in the Medical Reserve Corps, was reelected to the school board, March 22.

Tuberculosis Society Formed.—The Burlington County Antituberculosis Association was organized at Mount Holly, March 2, with Dr. Marcus W. Newcomb, Brown Mills, president.

NEW YORK

Brooklyn Hospital Needs Funds.—The Holy Family Hospital, Brooklyn, has started a campaign to raise $5,000 with which to purchase new ambulances and other equipment. The ambulances of this hospital answered 3,213 calls in 1917.

Licenses Revoked.—At a meeting held March 28, the New York Board of Regents revoked the licenses of Dr. William L. Owen of New York City and Dr. Henry Seligman of Brooklyn. Dr. Owen was recently convicted of repeatedly failing to record the disposition of heroin and has been sentenced to the federal prison at Atlanta, Ga. Dr. Seligman was convicted of conspiracy in an attempt to discharge and exempt Joseph Levy from the requirements of the selective service act.

War Hospital at Mineola.—Announcement was made, April 4, that the fair grounds at Mineola, L. I., will be turned over to the government for a convalescent hospital. They comprise 63 acres which have been used as an aviation field. When the present buildings have been remodeled, they will house 10,000 patients. At present convalescents from the various army cantonments will be cared for, but later it is probable that the institution will be used for soldiers returning from overseas.

New York City

Personal.—Dr. Stephen Smith has resigned as a member of the state board of charities. During the period since 1881, with the exception of six years, from 1882 to 1888, when he was a member of the state commission on lunacy, Dr. Smith has served continuously on the board. He was 95 years old, February 19.

Investigate Powdered Glass Reports.—The New York City Health Department has analyzed in its laboratory more than 100 samples of bread, rolls, candy and other foodstuffs said to contain powdered glass. No glass was found. Fifty per cent. of the samples contained sand or grit. The department states that in normal times only 5 per cent. of persons finding sand or grit in their food would report it, while at the present time 75 or 80 per cent. would report the fact to the department. The department warns the public against the wave of hysteria that seems to be the result of these unfounded reports.

NORTH DAKOTA

Hospital Opened.—The new main building of Parrott Hospital, Winston-Salem, which was recently completed at a cost of more than $65,000, has been opened to receive patients.

Clean-Up Week.—The period from April 5 to April 20, has been set apart as the time in which there is to be throughout the state a general clean-up of all waste material that might harbor disease germs. The state authorities ask that the municipalities cooperate with them in this laudable sanitary endeavor.

OHIO

Army Tuberculosis Victims.—The state is short of funds to erect two required buildings at the Mount Vernon Tuberculosis Sanatorium to care for men discharged from the Army for tuberculosis. To an inquiry from the state, the War Department has responded that it regards the state as responsible for the care of these patients, and the state is looking to the Red Cross to provide funds to the amount of $50,000 for the necessary buildings.

State Venereal Disease Campaign.—The state department of health has announced the details of its campaign against venereal diseases in conformity with the plan of the federal authorities for suppressing these diseases, and Dr. H. N. Cole, of Western Reserve University, Cleveland, has been placed in charge. The campaign will be carried on purely as a matter of public health, divorced from all moral issues. The cities will cooperate with their separate organizations. The campaign will include such measures as education through placards and leaflets, a bureau of sex advice, free Wassermann and other laboratory tests, cooperation with local authorities in organizing clinics and providing hospital beds, and cooperation with the military authorities in locating and treating sources of infection.

PENNSYLVANIA

Personal.—Dr. William H. Glick has resigned as medical inspector of the Bethlehem public schools.——The successor of the late Samuel G. Dixon, commissioner of health has not yet been appointed. Among those reported to be recommended for the position are: Dr. Wilmer Krusen, health director of Philadelphia; Dr. E. G. Davis, head of the medical advisory board in the draft service, and Dr. Edgar M. Green of Easton.

Miscellaneous.—A systematic effort throughout the state to ascertain the opinion of physicians regarding the present compensation law is being made. The law at present allows compensation to physicians for fourteen days. Many physicians think this time should be lengthened to twenty-one or thirty days. This was the consensus of opinion at a meeting of the Westmoreland County Medical Society, at which the law was discussed.

Philadelphia

Charitable Bequests.—The will of the late Henrietta A. Widdafield directs that a trust fund of $25,000, which is to be held for her husband until his death, shall then be divided among various charitable institutions and $5,000 will go to the Women's Homeopathic Association.——The St. Vincent's Home and Maternity Hospital will benefit to a large extent in the estate of the late James P. McMahon, who left an estate of $13,000 to be divided between a number of charitable institutions.

Pennsylvania Hospital Off.—Base Hospital Unit No. 20 of the University of Pennsylvania left Philadelphia on April 1 on the beginning of its journey to France. The unit was organized last fall and started training, November 1. It consists of 150 men of whom probably more are athletes than in any other similar organization of men sent to France from this country. Major John B. Carnett is the medical head of the unit and his staff includes Major George M. Piersol, former surgeon at Camp Dix, Wrightstown, N. J., Capts. T. M. Edwards and William Bates who had charge of the field hospital at Fort Oglethorpe, Ga. The military commander is Major Thomas H. Johnson, U. S. Army.

RHODE ISLAND

Election of Officers.—At the meeting of the Pawtucket Medical Association at Pawtucket, the following officers were elected: Dr. Ardashes H. Merdinyan, president; Dr. Earl J. Mathewson, vice president; Dr. Conrad E. Thibodeau, secretary, and Dr. Stephen F. Hughes, treasurer.

Examinations of Practitioners, Etc.—In future examinations of candidates to practice medicine in the state, practical as well as written examinations will be required.——An appropriation of $1,000 has been asked for by the state board of health to stop illegal practice in the state.——Blanks have been sent out to all physicians on which to report venereal disease which have now been made reportable to the state board.

SOUTH DAKOTA

Officers Elected.—At the meeting of the state board of health and the state medical examiners at Pierre, Dr. Hampton Kenaston, Bonesteel, was made president; Dr. Charles E. McCauley, Aberdeen, vice president, and Dr. Park B. Jenkins, Waubay, secretary. The other members of the board are Dr. Arthur S. Jackson, Lead, Charles A. Bower, Mitchell. At the meeting, eleven applicants took the examination for licenses.

Personal.—Dr. Thomas B. Christian, South Bend, Ind., bacteriologist and pathologist, has been appointed city health officer of Aberdeen.——Dr. Daniel L. Scanlan has been elected president of the Volga Hospital Association which conducts a cooperative hospital.——Dr. Albert Sherrill, Camp Crook, suffered the loss of a finger on his left hand which had to be amputated on account of blood poison.——At a recent meeting of the Black Hills Medical Association, Dr. John W. Freeman, Lead, who recently retired as a member of the staff of the Homestake Hospital, was presented with a bronze loving cup suitably engraved. Honorary memberships in the association and in the state association were conferred on Dr. Freeman.——Dr. Charles E. McCauley, Aberdeen, a member of the state board of health has been given charge of the work of enforcement of war measures in regard to venereal disease. He has appointed as assistant Dr. Robert S. Hart, Groton.

WASHINGTON

Miscellaneous.—At Spokane, work on the new $100,000 tuberculosis sanatorium at Edgecliff was started, March 18. ——The physicians of Everett, March 17, decided to shorten their working hours in order to keep up their civic, professional and patriotic duties during the war. They will close their offices in the evening.

Personal.—The mayor of Tacoma has appointed Dr. Edwin A. Layton health commissioner of schools and city health officer. The city council will give Dr. Layton a fund of $5,000 to be expended within the next thirty or sixty days to combat communicable diseases.——Dr. John B. Anderson, city health officer of Spokane, visited Portland, March 21, to study the details of Portland's system of handling and treating women suffering from social diseases, with the view of inaugurating a similar plan in Spokane.

WISCONSIN

Free Dental Work.—Among the cities in the state having provision for free dental work for schoolchildren not able to pay for such work are Milwaukee, Oshkosh, Racine, Janesville, Madison and Wausau.

Officers Elected.—At the meeting of the Fox River Valley Medical Society at Green Bay, Dr. Victor F. Marshall, Appleton, was elected president; Dr. Maurice D. Bird, Marinette, first vice president; Dr. Alfred P. Holz, Seymour, second vice president; Dr. Emile G. Nadeau, Green Bay, secretary-treasurer, and Dr. Charles J. Chloupek, Green Bay, was reelected censor.

Residential Sewage Disposal.—The October-December (1917) number of the state board of health *Bulletin* gives plans with details and numerous illustrations for water supply systems and sewage disposal plants for dwellings in unsewered towns and country districts. The plans for sewage disposal provide for tank disposal, dry-well, filter bed and spray disposal of effluent, etc., with specifications of materials required, and advice as to the best method of installation.

CANADA

Public Health Department for New Brunswick.—The question of the establishment of a department of public health for New Brunswick is under consideration by the legislature of that province.

Personal.—Col. Charles A. Hodgetts, Ottawa, medical adviser to the Canadian Conservation Commission, who has been overseas for three years or more as Red Cross commissioner, has resigned and his resignation has been accepted.

General News.—The Ontario Temperance Act has been amended in that section relating to physicians writing prescriptions for medicinal purposes. The law now requires that, when writing an order on the vendor, the physician must attach thereto a certificate to the effect that "the quantity of liquor therein mentioned is the minimum quantity necessary for the patient for whom it is ordered."——Fifth year medical students of McGill University, Montreal, will again dispense with their summer holidays this year, and by studying until next autumn will win their degrees earlier and go overseas with the Canadian Army Medical Corps. The request for this was made by the students themselves, of whom there are seventy-one enrolled in the class.——Free distribution of diphtheritic antitoxin was begun in the province of Saskatchewan last September.

GENERAL

Bequests and Donations.—The following bequests and donations have recently been announced:

The United Hebrew Charities, New York City, $400,000, other Jewish charities from $6,000 to $75,000, amounting to more than $1,000,000, after the death of testator's widow, by the will of Ludwig Dreyfus, New York City.

Examination of Unduly Toxic Arsphenamin by Hygienic Laboratory.—In view of the reports in current medical literature of untoward results from the use of arsphenamin and neo-arsphenamin, Dr. G. W. McCoy, director, Hygienic Laboratory, Washington, D. C., requests that samples of any lots of these arsenicals which have shown undue toxicity be forwarded to the Hygienic Laboratory for examination. In sending these samples it should be ascertained that the lot number is the same as that of the ampules used on patients. The samples sent should, if possible, be accompanied by a brief note stating the approximate body weight and age of the patient, the dose and dilution of the drug given, the symptoms and result; that is, whether fatal or not.

A Warning.—The Journal has repeatedly published warnings against fraudulent canvassers and collectors. The most frequently worked swindle during the past few years has been an attempt to secure subscriptions on the grounds that the solicitor is a contestant for a prize in the form of a scholarship in some educational institution to be awarded to the one who sends in the most business in a certain length of time. This scheme has been worked under the names of the Cornell Educational Association, the Michigan Educational Association, the National Educational Association, the National Society of Universities, etc. The most recent is from Kokomo, Ind., where a physician has been swindled by a solicitor working under the name of the Pennsylvania Engineering Committee of Pittsburgh. Again we remind our readers that no one is authorized to solicit subscriptions or collect money for any of the publications of the American Medical Association unless he carries credentials bearing the seal of the Association.

CENTRAL AND SOUTH AMERICA

Public Health in Honduras.—It is announced that a Direccion General de Salubridad has been created in Honduras.

Prohibition in Colombia.—The authorities in Colombia are studying the question of drastic legislation for repression of alcoholism.

Ankylostomiasis in Ecuador.—The government of Ecuador has recently voted funds to enable the public health service to carry on an active campaign against this disease.

Prohibition in Peru.—The legislature has recently passed a law which has been signed by the president and which prohibits the sale of alcoholic liquors on Saturdays and Sundays.

Medical School in Paraguay.—The medical department of the national university of Paraguay, at Asuncion, has been closed for some time. Steps are now being taken to reopen it.

Lenthening of the Medical Course in Uruguay.—The *Cronica* of Havana states that the medical department of the University of Montevideo has petitioned the government to lengthen the medical course to seven years.

Banquet to Professor Gastañeta.—In New York, the Rockefeller Institute recently tendered a banquet to Dr. G. Gastañeta, subdean of the medical department of the University of Lima, Peru, who has been on a brief visit to the United States.

Scholarship for Nicaragua Student.—The Rockefeller Foundation has awarded a scholarship to Miss de Estrada of Nicaragua to continue her studies in bacteriology, tropical medicine and preventive medicine at the University of Pennsylvania and at Johns Hopkins.

Interchange of Professors.—Drs. C. Chagas and V. Brasil of Rio de Janeiro have been appointed by the Rockefeller Foundation president and secretary of the consulting board for Brazil to pass on the professors for interchange and the candidates for the Foundation's pensions.

Garcia Treatment of Leprosy a Failure.—A committee appointed by the Academia de Ciencias of Cuba to study the Garcia plan of treatment of leprosy has reported that the Hansen bacilli were found still in the lymph and mucous secretions of patients after a thorough course of this treatment, and the improvement in the general health observed in some of the patients was no more than can be realized by the usual measures. The verdict was therefore unfavorable.

Antivenereal Dispensaries at Montevideo.—Five conveniently located and well equipped free dispensaries have been opened at various points in Montevideo, in addition to the central dispensary, for consultation and treatment in venereal diseases. They are installed in hospitals or similar public institutions, and are in charge of specialists selected by the Consejo Nacional de Higiene or the Asistencia Publica. No discrimination is to be made as to social station among the applicants. The work is under the auspices of the board of the Asistencia Publica Nacional, of which Dr. Martirene is president.

The Medical Journals of South and Central America.—In every one of the twenty-one countries of South and Central America from one to twenty-three medical, pharmaceutical, dental or veterinary journals are published regularly. Brazil has the largest number, Cuba has twenty-two, and Argentina sixteen. A list of 104 was recently published in the *Vida Nueva* of Cuba—a total of seventy-seven strictly medical journals and four or five pharmaceutical in the twenty republics south of the United States. Their articles are authorities on tropical medicine, snake bites, leishmaniasis, echinococcus disease and a number of other lines in medicine. Now that the German medical journals are in eclipse, so far as America is concerned, the world begins to realize that much of the prestige of the German medical journals was due to the fact that the exceptionally important articles by workers in other lands were often sent to be published in German medical journals at the same time that they were published in the writers' home journals. Naturally, the German medical journals got the credit for the articles because they had a wider circulation.

FOREIGN

Pneumonic Plague in China.—Dr. Percy T. Watson, in charge of the medical work of the American Board of Commissioners for foreign missions at Fanchow, states that the plague of pneumonia which has recently appeared in Mongolia, and in that part of the Shang-Si province which is north of the great wall, has been definitely demonstrated to be pneumonic plague.

Testimonial to Pekelharing.—The seventieth birthday of the well known authority on physiologic chemistry and histology, Prof. C. A. Pekelharing, of the University of Utrecht, falls on July 18, and his friends and pupils are collecting a fund to erect a tablet in his honor or endow the laboratory for physiologic chemistry there. Besides his early work on beriberi, fibrin ferment and the functions of the lymphoid tissue, he has recently published works on the influence of inorganic salts on the lipase of the pancreas, of phosphatids on coagulation, on the activation of blood serum, etc. The secretary of the committee in charge of the testimonial is Dr. C. J. van Hoogenhuyze, Banstraat 8, Amsterdam.

Deaths in the Profession Abroad.—G. Filomusi-Guelfi, professor of legal medicine at the University of Pavia and author of numerous works on forensic medicine, aged 62.——G. A. Petrone, docent in pediatrics at the University of Naples, aged 44.——The *Nederlandsch Tijdschrift* reports the death of the physiologist, Prof. **E. Hering** of Leipzig, aged 84. He occupied the chair of physiology at Vienna and Prague for a time but has been connected with the University of Leipzig since 1895. Some of his numerous works on physiology have been translated into other languages, including his "Memory and the Specific Energies of the Nervous System."——It reports further the death of the urologist, Prof. **H. Lohnstein** of Berlin, editor of the *Allg. med. Central-Zeitung* and founder in 1895, with Casper, of the *Monatsberichte der Krkten des Harn- und Sexualapparates*, aged 53.——**D. E. Sulzer**, a leading ophthalmologist of Paris, on the editorial staff of the *Annales d'Oculistique*, aged 60.——**T. de Speyr**, also a well known Swiss ophthalmologist, residing at Chaux-de-Fonds, aged 50.

CORRECTION

Distinguished Service Award.—We are informed that the award mentioned April 6, p. 1006, was to Lieut. Raymond Neel Davis, M. R. C., formerly of South Carolina.

PARIS LETTER

Paris, March 7, 1918.

Prostheses for the War Cripples

In order that a war invalid who has a crippled arm or leg or a stump may take up useful work, he has to be supplied with an appropriate apparatus. The minister of war regards a prosthesis of this kind as an integral part of the care which should be given the wounded by the Service de Santé. His aim is to give each war invalid an artificial arm or leg, not merely the simplest form, the peg leg, but in each case the apparatus needed to overcome the effects of the mutilation so that the man can practice a trade or other remunerative occupation. It must be realized, however, that the carrying out of this ideal is far from being an easy matter, not only on account of the expense but also because of the lack of workmen to make the artificial limbs. When the state issued these orders, the delivery of the needed appliance was delayed in some instances for a long time, so that more than once the Service de Santé was forced to let these mutilated men who needed an artificial leg leave with a peg leg, stiff and hard. To be sure, private initiative and funds have supplemented and completed the work of the state. One of these institutions is the Fédération nationale d'Assistance aux mutilés des Armées de terre et de mer, which was established toward the end of 1914 and has since donated these appliances to the war cripples. Although the minister of war had requisitioned the entire production of prostheses, at the request of the federation, he authorized the manufacture of apparatus after an examination of each case. The federation has also adopted the principle of donating apparatus only when the prosthesis furnished by the state is insufficient to meet the professional needs of the patient. In fact, its activities are restricted almost entirely to those mutilated who have had a limb or limbs amputated and who are resident in the schools of reeducation and whose special needs the federation is able to appreciate thoroughly.

EVOLUTION IN CONSTRUCTION OF PROSTHESES

It is interesting to note the evolution that has taken place since the beginning of the war in the construction of these appliances for the mutilated. At first, the complicated prostheses, fragile and cumbersome, were considered to be veritable prodigies of ingenuity. Now these complicated appliances have been discarded by the great institutions in France for vocational rehabilitation of the wounded, as well as by the industrial establishments which employ these mutilated. The principle held in view is that the patient should rely mainly on what physical aptitude he has left, and when he has to use an orthopedic appliance, it should be a simple apparatus, solid, not expensive, one which can be replaced or repaired easily. At first the aim was to construct a sort of universal claw (*pince universelle*) in cases of mutilation of the upper extremity so as to have an apparatus that will be useful generally and supply all needs. Among the more ingenious apparatus of this kind are the claw of Dr. Amar, the claw of Louis Lumière, and the claw d'Estor. All these appliances are of value. They enable the wearer, with experience and training, to do certain kinds of work with some skill, as, for instance, the work of a joiner or a fitter. On the other hand, these appliances are not suited for the agriculturist. It must be remembered, however, that it is impossible to create an apparatus that is suitable for all occupations. In each trade it is necessary to supply the mutilated with a carrying tool or claws of various forms adapted to the different needs.

WORKING "HANDS"

This has led to the designing of artificial working hands, *mains de travail.* There is the hand of the gardener; the hand of the wine grower; the hand of the laborer, and the hand of the digger; the hand of the joiner, the chair caner, the jeweler, the printer, the letter carrier, and even the mechanician. These artificial working hands do not conform to the shape of the anatomic hand. The mechanism is extremely simple, often rudimentary, not expensive, but adapted to the complementary movements that the patient needs. The object is not to restore the anatomic shape, but to restore function. How were the *mains de travail* created? The thing is very simple. When the mutilation involves the right arm, the man should first be taught to become left handed, that is to say, he should learn to use his left hand just as well as he formerly used his right. This once accomplished, it follows that after loss of one arm, either the right or the left, there is need to supply only the missing arm or hand. Consequently, one need only create a complementary left member, a simple auxiliary of a healthy right arm. It is sufficient, to meet the exigencies of any trade, to specify the functions of the left hand during the course of working, and to seek artificial means to supply that left hand. For this it was necessary to study at first on normal, nonmutilated workers the movements, attitudes and different positions of the left hand in each trade. By dissecting thus, as it were, carefully the various phases of the work of the left hand it was possible to trace, step by step, all the things that the left hand had to do in the practice of the trade. It was found, strange to say, that the movements of the left hand, in general, are very simple, not very numerous, acting only along a single axis and often in a constant direction. It was this method of dissociation of the movements that has enabled Dr. Boureau to supply a left hand for many trades with the aid of one or two simple devices. He has thus created a whole series of *mains de travail* which are very ingenious and which render excellent service, notably for the readaptation of the mutilated for agricultural work.

Death of Dr. Barety

Dr. Alexander Barety, former intern in the hospitals of Paris, administrator of civil hospitals, former vice president of the Conseil général des Alpes-Maritimes, recently died in Nice, aged 74.

LONDON LETTER

London, March 12, 1918.

Compulsory Rations

As stated in a previous letter, a system of compulsory rationing is in vogue for the whole civilian population. The allowance per week is 1¼ pounds of meat, 4 ounces of butter or margarin, and 8 ounces of sugar. Other articles of diet, such as bread or fish, have not yet been rationed. A general scheme such as this cannot be applied to every person regardless of health or the work performed. It has been found necessary, therefore, to introduce the following regulations on the advice of the Committee of Reference of the Royal College of Physicians and of Surgeons, and of the Central Medical War Committee, that for the time being these can be allowed only as follows: 1. Extra sugar shall be allowed only those persons having difficulty in swallowing solids because of organic disease, for example, in cancer of the tongue, cancer of the esophagus, and gunshot wounds of the jaws. 2. Extra meat and fat may be allowed for patients suffering from diabetes and from tuberculosis, and also from celiac disease and pancreatic insufficiency. No extra meat can be allowed for making beef juice, beef tea or broth. 3. Priority may be granted for milk as follows: In cases of acute illness, for example, pneumonia, typhoid and acute abdominal conditions, the physician in attendance may give a certificate, on the receipt of which the milkman shall be empowered to supply the quantity of milk for one week. This certificate shall not extend for longer than one week, unless permission has been obtained from the local food office. Extra milk may also be allowed for pregnant and suckling women, for invalids suffering from the following chronic diseases: nephritis, tuberculosis, certain gastric and intestinal conditions, for example, gastric and duodenal ulcers, gastrostaxis, enteritis, dysentery and diarrhea; recognized diseases and disorders associated with malnutrition, and for patients who are unable to take solid food. There is no disease for which cream is allowed. For tuberculous persons in sanatoriums and hospitals, the following is the weekly allowance:

WEEKLY ALLOWANCE FOR TUBERCULOUS

	For Persons without Much Constitutional Disturbance		For Persons with Constitutional Disturbance	
	Men	Women	Men	Women
Milk	14 pints	14 pints	21 pints	21 pints
Meat (including suet)	3½ lb.	3 lb.	3½ lb.	3 lb.
Bacon	½ lb.	½ lb.	½ lb.	½ lb.
Fish	½ lb.	½ lb.	1 lb.	1 lb.
Cheese	½ lb.	½ lb.	4 oz.	4 oz.
Oatmeal	½ lb.	½ lb.	½ lb.	½ lb.
Pulses	½ lb.	½ lb.	.....	.....
Bread	4 lb.	3 lb.	3 lb.	3 lb.
Flour	½ lb.	½ lb.	½ lb.	½ lb.
Potatoes	5 lb.	4 lb.	2 lb.	2 lb.
Cereals	¾ lb.	¾ lb.	¾ lb.	¾ lb.
Sugar	½ lb.	½ lb.	½ lb.	½ lb.
Jam, syrup, etc.	¾ lb.	¾ lb.	¾ lb.	¾ lb.
Margarin and other fats	10 oz.	10 oz.	10 oz.	10 oz.

The scale for children under 10 will be three fifths of the corresponding scale for the adult woman. It will thus be seen that the dietaries for the tuberculous considerably exceed the allowances for the general population.

The Future of the International Red Cross

In my last letter the torpedoing of the seventh hospital ship by the Germans was described. It is feared that there is no longer any doubt that seven officers and forty-seven of other ranks of the Army Medical Corps as well as eight women nurses have lost their lives. In the face of this barbarity the *British Medical Journal* asks, What is to become of the International Red Cross? Germany, which was a party to the conventions, has persistently broken, both on sea and on land, all her undertakings. Can she be admitted to any international organization of the Red Cross in the future? What guarantees can she give that any nation can accept? Further, what is the position of the Austrian Red Cross? It held an international Red Cross conference less than a year before the war, and though few atrocities have been traced to the Austrian empire, it has supported the Germans through thick and thin.

Smallpox in London

An outbreak of smallpox has occurred in the East End of London. Six cases have been reported. The public health authorities, especially those responsible for soldiers in training camps, are making every effort to localize the outbreak, and the soldiers have been warned about approaching the infected area.

Deaths

Ernest Charles Reyer, Indianapolis; Medical College of Indiana, Indianapolis, 1885; Bellevue Hospital Medical College, New York City, 1889; aged 53; formerly a Fellow of the American Medical Association; a member of the Indiana State Medical Association; formerly president of the board of health and charities in Indianapolis, and professor of diseases of the mind and nervous system in the Medical College of Indiana; died suddenly at his home, March 24, as a result of injuries suffered in a fall.

William Ogden McDonald, Brooklyn; New York Medical College, New York City, 1855; aged 81; a veteran of the Civil War; a pension examiner from 1877 to 1884, and later professor of anatomy and gynecology in the New York Homeopathic Medical College; a member of the American Institute of Homeopathy; died at his home, March 25, from *senile debility.*

Percival Lantz, Alaska, W. Va.; College of Physicians and Surgeons, Baltimore, 1891; aged 46; formerly a Fellow of the American Medical Association; a member of the West Virginia State Medical Association; formerly postmaster of Frankford, W. Va.; died at the South Baltimore Eye, Ear and Throat Hospital, March 23, from acute nephritis.

Died in the Service

WHILE ON FURLOUGH FROM CAMP WHEELER

Capt. Samuel Chandler Baker, M. R. C., U. S. Army, 1867-1918

(*See The Journal, April 6, p. 1023*)

William Aloysius Dunn, Boston; Harvard University Medical School, Boston, 1875; aged 64; a member of the Massachusetts Medical Society; formerly a trustee for the Institution for the Feebleminded and the Boston City Hospital; for six years a member of the school board; died at St. Vincent's Hospital, New York City, March 28.

Charles Harvey Glidden, Little Falls, N. Y.; College of Physicians and Surgeons, Columbia University, New York City, 1881; aged 61; a Fellow of the American Medical Association; a member of the staff of the Little Falls Hospital; died while on a visit to his sister in Holley, N. Y., March 25.

William Eugene Buell, San Francisco; College of Physicians and Surgeons, San Francisco, 1900; aged 42; formerly a Fellow of the American Medical Association; died at the Union Iron Works Company Employees Hospital, San Francisco, February 4.

Rolandus G. Walker, Denver; Cleveland College of Physicians and Surgeons, 1904; aged 50; formerly a Fellow of the

American Medical Association; a member of the Colorado State Medical Society; died at his home, March 21, from pneumonia.

Lemuel Offut, Greensburg, Pa.; University of Maryland, School of Medicine, Baltimore, 1876; aged 66; a Fellow of the American Medical Association; at one time president of the Westmoreland (Pa.) Hospital staff; died at his home, March 25.

Lieut. Mark Beach, M. R. C., U. S. Army, Clinton, Kan.; Kansas Medical College, Topeka, 1903; aged 44; formerly a Fellow of the American Medical Association; a member of the Kansas Medical Society; died at Fort Sill, Okla., February 15.

Edward James Caldwell, West Chester, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1902; aged 45; formerly a member of the Iowa State Medical Society; died at his home, March 21, from Bright's disease.

Alexander A. E. McCandless, Pittsburgh; Jefferson Medical College, Philadelphia, 1870; aged 68; former coroner, treasurer and sheriff of Allegheny County; died in the Allegheny General Hospital, Pittsburgh, March 23, from pneumonia.

Capt. Harry James O'Bryan, M. C., Minn. N. G., Watertown, S. D.; Barnes Medical College, St. Louis, 1902; aged 49; a Fellow of the American Medical Association; died on duty at Fort Snelling, Minn., April 3, from pneumonia.

John Henry Joyce, Buffalo, Texas; Missouri Medical College, St. Louis, 1877; aged 63; formerly a Fellow of the American Medical Association; a member of the Texas State Medical Association; died at his home, March 23.

Died in the Service
AT FORT SILL, OKLA.
LIEUT. MARK BEACH,
M. R. C., U. S. A.,
1874-1918

Saram R. Ellison, New York City; McGill University, Faculty of Medicine, Montreal, 1873; aged 66; formerly a member of the Medical Society of the State of New York; died at his home, March 26, from pneumonia.

Columbus Epaminondas McCoy, Bozeman, Mont.; Vanderbilt University Medical Department, Nashville, Tenn., 1895; aged 46; a Fellow of the American Medical Association; died at his home, March 22, from aneurysm.

James Robert Kistler, Kansas City, Mo.; Jefferson Medical College, 1879; aged 63; formerly a member of the Missouri State Medical Association; died at his home, March 23, from heart disease.

James Molland Greenslade, Lima, Ohio; Rush Medical College, Chicago, 1899; aged 65; for eleven years superintendent of the schools of Lima; died at the City Hospital, March 21.

Theron Dickey Lockhart, Chicago; Trinity Medical College, Toronto, 1896; aged 45; formerly a member of the Illinois State Medical Society; died in Birmingham, Ala., March 22.

George W. Grimes, Carlisle, Ky.; University of Kentucky, Medical Department, Louisville, 1883; aged 58; formerly a druggist; died at his home, March 22, from uremic poisoning.

Oscar August Bast, Brooklyn; Long Island College Hospital, Brooklyn, 1905; aged 35; founder of the Ridgewood Sanitarium; died at his home, March 27, from pneumonia.

John Augustus Walther, New York City; Columbia University, College of Physicians and Surgeons, New York City, 1876; died suddenly at the Memorial Hospital, March 27.

Marriages

CAPT. URBAN BUNYON HARRIS, M. R. C., U. S. Army, on duty at Camp Funston, Kan., to Miss Mary Holabird, both of Chicago, March 30.

MATHILDA OLSEN ENNIS, Chicago, to Mr. George A. Cowden of El Centro, Calif., at San Diego, Calif., January 1.

LIEUT. JAMES WALTER WELLS, M. C., Ill. N. G., to Miss Melissa Kirkpatrick, both of Waltonville, Ill., March 22.

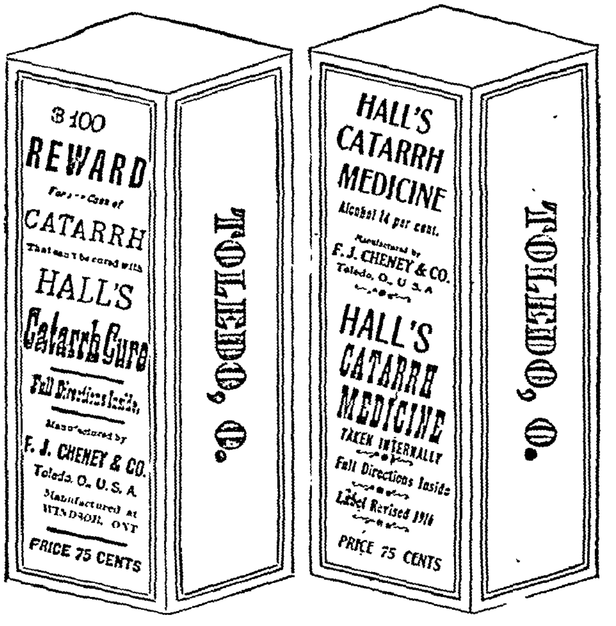
HALL'S CATARRH CURE

Another Victim Tries to Get the Hundred Dollar Guarantee

"Hall's Catarrh Cure" is well known to readers of THE JOURNAL. This mixture of alcohol, potassium iodid, sugar and small amounts of some vegetable extractives has for many years been advertised under the claim that its manufacturers would pay "$100 Reward for any Case of Catarrh that can't be cured" by it. It was the manufacturer of "Hall's Catarrh Cure," Cheney, a power in the "patent medicine" world, who devised the "Red Clause." Mark Sullivan showed in *Collier's*, how this clause, when introduced into the advertising contracts made by "patent medicine" manufacturers with newspapers, effectually whipped the papers into line to defeat any public health legislation that might be inimical to the "patent medicine" business.



CANADA UNITED STATES

Photographic reproduction (reduced) of the labels of "Hall's Catarrh Medicine" as sold in Canada and the United States, respectively. Comparison of the labels shows that the presence and amount of alcohol is admitted where the law demands it (in the United States), but no mention is made of it in Canada. While the stuff is called a "cure" in Canada, where there is no penalty for false and fraudulent therapeutic claims, it is a "medicine" in the United States. In the United States also the "$100 Reward" does not appear on the trade package.

Long after the word "cure" had been taken off the labels and trade packages of the "patent medicines" made by the smaller fry in the nostrum world "Hall's Catarrh Cure" blatantly continued to defy the federal authorities. It is only within comparatively recent times that the name of the nostrum has been changed to "Hall's Catarrh Medicine" and this, as THE JOURNAL pointed out not long ago, only in the United States. It is still a "cure" in Canada!

The utter worthlessness of the hundred dollar "guarantee" to "cure catarrh" has been commented on before. Some years ago THE JOURNAL recounted the case of a man who, after taking twenty-six bottles of "Hall's Catarrh Cure" declared that he was worse instead of better and asked for the hundred dollars. F. J. Cheney & Co.'s reply was that they would "not feel at all justified in refunding the money paid for this trial [!] of the medicine" as "many cases require much more than you have taken for a cure"! Nearly three years ago we received a letter from a man who claimed to have taken thirteen bottles without results. He had written, he said, to the Cheney concern asking, not for the hundred dollars reward, but "for only one-half the price of the medicine." But: "They will not return a cent." The man was even so unsophisticated as to complain to his two home papers, that were carrying the Hall "guarantee," and expressed surprise that he was unable to get any satisfaction and, in fact, "the deceitful advertisements still appear in both papers."

Now come some letters from a Canadian, which speak for themselves:

> American Medical Association,
>
> *Dear Sirs:*—I heard of your Association through a circular published by the Metropolitan Life Insurance Co. I have catarrh and last July I commenced taking Hall's Catarrh Cure. After taking thirty (30) bottles of this medicine and receiving no benefit whatever, I wrote F. J. Cheney & Co. *re* their guarantee. They sent me the enclosed letter dated Dec. 20, 1917.

FOOD REPELLED FOR MANY YEARS

Cumberland Grocer Says Tanlac Brings Back His Lost Health

A. L. Wingert, 171 North Centre Street, had been in the grocery business for fifteen years in Cumberland, prior to his recent retirement because of ill health.

"I have not felt as I should in many years," declared Mr. Wingert. "I had absolutely no desire for food. Pains in the stomach and a dull listless feeling after eating were not uncommon. I sent for a bottle of Tanlac and began using it according to directions.

"Tanlac has done me a wonderful lot of good. My health is surely coming back to me. I have a ravenous tite and everything I eat digests erly—thanks to Tanlac. I sin. recommend Tanlac to anyone in berland who suffers as I did."

Tanlac is now being specially introduced and explained in Cumberland at Lichtenstein's drug store, by Mr Rivenburgh, the Tanlac Man.—Advertisement.

Address City.

Note: The writer of the testimonial had been dead nearly a week when his testimonial appeared.

> I answered this and received the one dated December 20, 1917. After some inquiry, I discovered that they could not advertise this medicine as a "cure" in the U. S. A., therefore, it is "Hall's Catarrh Medicine." I wrote and told them all this and also that it would not cure catarrh, and asked them to live up to the terms of their guarantee. In answer I received the letter dated March 7, 1918. *I am writing them today* enclosing a druggist's certificate that I bought and paid for the medicine, and a certificate from a local doctor that I am suffering from nothing except catarrh. I also told them I was taking the matter up with your Association.
>
> Any information which you might give me as to how to proceed would be appreciated. Can you tell me who to write to in the State Legislature in the Capital of Ohio?

Here is the letter of December 7, referred to above, received from F. J. Cheney & Co.:

> *Dear Sir:* It is very seldom that anyone takes as much medicine as you claim without deriving some benefit from its use. The only way we can account for this is that your trouble is complicated with some other disease, which, however slight, tends to retard the action of the medicine.
>
> Hall's Catarrh Cure will do what we claim for it,—cure catarrh or deafness caused by catarrh—and if your trouble is wholly catarrhal, we can see no reason why you as well as so many others cannot be cured by its use.
>
> Yours,
> F. J. Cheney & Co.

Here is the second letter, that of December 20:

> *Dear Sir:* As before stated, while many cases of catarrh have been greatly relieved by the amount of Hall's Catarrh Cure which you have taken, others require long continued treatment as cases vary and the medicine does not act alike upon all persons.
>
> Hall's Catarrh Cure will do what we claim for it,—cure catarrh or deafness caused by catarrh. We do not claim to cure any other disease.
>
> In your case, we would suggest that you increase the dose and see if you can obtain more relief from the larger doses. Of course, if the stomach should become deranged, decrease the dose. The addition of a third teaspoonful of ordinary baking soda in the water in which the medicine is taken is sometimes greatly beneficial.
>
> Our guarantee is just as advertised.
>
> Yours,
> F. J. Cheney & Co.

The last letter, that of March 7 and the gem of the collection, follows:

> *Dear Sir:* We have gone over your correspondence carefully and cannot find wherein you have stated anything whatever about your case. Kindly *write us fully stating symptoms of the disease, action of the medicine upon you, when you commenced taking Hall's Catarrh Medicine and when you discontinued its use.*
>
> In regard to our guarantee, will say that we require that *the patient prove that he has* catarrh not complicated with any other disease; that he has *taken strictly* according to directions a sufficient number of bottles of Hall's Catarrh Medicine to cure his particular case and that he has not been cured. We believe that these *restrictions* are fair and are only such as would be required in any business transaction.
>
> *Hall's Catarrh Cure and Hall's Catarrh Medicine are one and the same. The name will be changed in Canada* as soon as our advertising can be changed.
>
> Yours,
> F. J. Cheney & Co.

One gathers from the last letter of F. J. Cheney & Co. that before a victim can get his hundred dollars he has to prove (1) that he has taken enough Hall's Catarrh Cure "to cure his particular case" and (2) that his particular case "has not been cured"! Did ever a thimble rigger, caught at cheating, put up a flimsier defense?

Our Canadian correspondent's request that we suggest some one in the Ohio State Legislature to whom he might write relative to the matter *discussed must*, perforce, remain unanswered. Long experience has shown that state legislators are strongly averse to doing anything that will hurt local industries, especially when such industries are extensive advertisers in the local newspapers.

The information contained in the closing paragraph of the Cheney letter to the effect that Hall's Catarrh Cure and Hall's Catarrh Medicine are one and the same and that the Canadian labels will, before long, more nearly tell the truth, is interesting. We wonder whether the Cheney concern will also take off the Canadian label the hundred dollar "guarantee" *which now appears on it.* This guarantee does not appear on the United States label. Possibly the fact that the federal Food and Drugs Act makes lying on the label irksome may have something to do with it.

Health Officers.—An energetic health officer can control the local death rate if given a few years to do it; but to expect great results in the time he ordinarily holds office is beyond human power.—*Public Health*, Michigan.

Correspondence

"THE GROUND GLASS OBSESSION"

To the Editor:—The editorial with this title (The Journal, March 23, 1918, p. 852) I fear is far from the truth, especially in this part of the country. I wish you really knew how much there is going on along this line. Enclosed are a few cuttings; these are absolutely authentic reports from headquarters. If it stopped at ground glass it might be easy; but steel filings, stone, sand of a very irritating kind, aluminum or wire filings, and brassy metal powders have all been found, and chemicals, such as potassium bitartrate. In fact, it is a growing evil, and it does not stop at flour stuffs. We reported to the attorney's office cases of delicatessen canned goods all "doctored," and had a big round up this week after a most serious finding. I regret the necessity of asking you to withhold my name from publication for this time, but I am an old member and am on war and secret service work, and after the continual fires and explosions here, we cannot be too careful. In fact, we are not sufficiently careful in our subways and other important points. Hence, I advise research in lines scarcely dreamed of, and I am sure Prof. E. M. Chamot of Cornell can bear me out in this. There is urgent need of work of a microchemical nature, for example, in the steel and wood work of aircraft. In these, supports have been cut and lead substituted in such a way as to be undiscovered except by metallomicro-analysis. In one instance this resulted in three machines coming down and killing our boys. Hence, as a matter of government, war and medical necessity, The Journal, our standby and support in this great medical, scientific and serious work, should urge closer and more careful work and far more methods of discovery to combat this powerful and wide awake enemy.

An Army Surgeon.

THE USE OF IODIN IN THE PREPARATION OF THE PATIENT FOR DELIVERY

To the Editor:—The use of tincture of iodin in the preparation for abdominal section has become so general that its value as an antiseptic is well established. That its use in obstetrics has not become more general is surprising, especially when its many advantages are considered. The maintenance of asepsis even in the normal delivery offers many problems that are not encountered in surgical work.

The main objection to the use of iodin in this connection seems to be that first, many skins in the region of the vulva cannot tolerate its use, and secondly, many patients complain bitterly of burning and smarting subsequent to its application.

During the past few months at the Grace Hospital we have used several preparations or strengths of the tincture and have concluded that tincture of iodin, one-third strength, or tincture of Iodine, U. S. P., one part, Alcohol, two parts, offers a preparation that is almost ideal for use in obstetric work. Tincture of iodin of this strength has been used in the preparation for delivery of nearly 200 patients, and in no instance have there been any signs of dermatitis or any complaint of undue smarting or burning on the part of the patients. I have also used this preparation as a final procedure for delivery in private practice practically as a routine measure during the past four months.

At the hospital our technic of preparation of the patient for normal delivery is as follows: At the onset of labor the usual bath and enema are given, and the patient is clipped and shaved at the vulva. At the time of delivery or vaginal examination, the vulva and inner thighs are washed carefully with sterile green soap and sterile warm water. The vulva and thighs are now irrigated from above with 2 quarts of mercuric chlorid, 1 : 1,000, poured from a pitcher. If delivery is not to follow immediately, a sterile towel is wrung out in the mercuric chlorid solution and folded over the vulva. If, however, delivery is to follow shortly, the skin and vulva are dried by means of a cotton sponge on a stick and the preparation of iodin described above is applied by this same means. An area about 9 inches square should be covered beginning at the labia, then to the mons, the inner surface of the thighs, and lastly the anus. Every point within the area should be covered by the stain. The sterile drapings are now put in place by the physician or nurse so that only those parts of the vulva and thighs that have been stained are exposed.

By means of this painting or staining and only by this means are we positive that every part of our field has been treated by a suitable antiseptic. We can see just what has been covered.

I feel that the iodin in this connection gives a finishing touch to our preparation that makes for better technic, and that this extra precaution against infection gives added assurance to the obstetrician.

In cases of precipitate birth in which, owing to lack of time, the proper preparation is impossible, it is nearly always possible to use the iodin at least.

It seems to me also that if the iodin preparation could become more general in patients in poor surroundings, among midwives and the like, owing to its staining properties disinfection might be made more thorough.

Herbert Thoms, M.D., New Haven, Conn.

OPPOSITION TO THE NEW YORK HEALTH INSURANCE BILL

To the Editor:—The Journal (April 6, 1918, p. 1017) states that on the hearing on the New York health insurance bill, the bill had "the unanimous endorsement of the State Federation of Labor, the Women's Municipal League, Women's Trade Union League, and the Consumer's League of New York."

It ought to be of interest to the readers of a purely medical journal to hear that this bill was opposed by every county medical society in New York State as represented by Dr. Henry Lyle Winter, chairman of the Committee on Economics of the state society, and also by Dr. James F. Raney, chairman of the Legislative Committee of the state society. The New York County Medical Society had four representatives to voice its opposition. The city of New York was represented by its new health commissioner, Dr. J. L. Amster, also in opposition to that bill. These are facts that others like myself, members of the American Medical Association and patrons of The Journal, are entitled to know as matters of vital interest and important news.

John P. Davin, M.D., New York.

PREVENTION OF BLOOD CLOTTING BY DAKIN'S SODIUM HYPOCHLORITE SOLUTION

To the Editor:—We wish to record here very briefly a few facts with regard to the action of Dakin's solution on clotting. The solution used was obtained from the War Demonstration Hospital (Rockefeller Institute) freshly prepared every morning. Dog's, cat's and rabbit's blood flowed from an artery directly into Dakin's solution, one part of Dakin's solution to every five parts of blood. Such blood remains unclotted for ten or more days. For older solutions larger proportions must be used. The addition of a sufficient quantity of a calcium salt does not produce clotting. Neither does the blood become clotted by the addition of a foreign body, nor does fibrin form by whipping. The solution in this proportion produces a gradual laking of the red cells. When blood is drawn into an oxalate and centrifugalized, a clear plasma is obtained; when Dakin's solution is added to such plasma and the oxalate then neutralized by calcium salts, a clear, unclotted solution is obtained which can be kept for some time.

The addition of a tissue extract (thromboplastic substance, Howell) causes clotting of blood with Dakin's solution at any time. Blood which runs into Dakin's solution over body tissues is likely to clot. Whipping of blood kept fluid by Dakin's solution does not prevent subsequent clotting by tissue extract. The prevention of clotting by Dakin's solution is evidently due to its action on the thrombin. Dakin's solution does not seem to prevent clotting of guinea-pig's blood in the proportion effective for dogs and rabbits. Blood of rabbits which received epinephrin clots in Dakin's solution within twenty-four hours.

The blood of dogs or rabbits which received intravenously Dakin's solution in the proportion of 7.5 c.c. to 1 kg. of body weight, drawn within four hours of the injection and kept at room temperature, remains fluid for several days. As a rule, such animals succumb sooner or later to such an injection. The sodium hypochlorite solution which we received from the hospital was slightly alkaline, but a simple alkaline solution equal in alkalinity to such a solution did not prevent clotting.

Our observations have among others the following practical significance: Dakin's solution employed in wounds with capillary bleeding does not sustain the continuation of a hemorrhage. This is probably on account of the presence of tissue fluid which neutralizes the anticoagulating effect of the solution employed. A detailed report will appear in the *Journal of Experimental Medicine.*

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CHRONOLOGIC SCIENTIFIC DATA

To the Editor:—I am desirous of obtaining information as to the exact dates of certain events in medical history. If possible, please furnish me with the information requested below:

1. Exact date on which Dr. O. W. Holmes published his paper, discussing the contagious nature of puerperal fever.
2. Exact date in 1888 on which the Pasteur Institute was established.
3. Exact date in 1885 on which Pasteur began inoculation against hydrophobia.
4. Exact date in 1894 on which the use of diphtheritic serum was announced.
5. Exact date on which typhoid vaccination was announced.
6. Exact date on which chloroform was first used as an anesthetic.
7. Exact date in May, 1905, on which the discovery of the organism causing syphilis was announced.
8. Exact date on which American Medical Association was organized.
9. Exact date on which American Red Cross was organized.

R. C. Williams, M.D., Assistant Surgeon, U. S. P. H. S., Miami, Ariz.

Answer.—1. Feb. 13, 1843, Oliver Wendell Holmes read to the Boston Society for Medical Improvement his paper on "The Contagiousness of Puerperal Fever," which was published in the *New England Quarterly Journal of Medicine and Surgery,* April, 1843.

2. Nov. 13, 1888.

3. July 6, 1885.

4. *Deutsche medizinische Wochenschrift,* Dec. 4, 1890.

5. *Deutsche medizinische Wochenschrift,* Nov. 12, 1896.

6. Nov. 10, 1847.

7. Published simultaneously in the *Deutsche medizinische Wochenschrift,* May 4, 1905, and in the *Berliner klinische Wochenschrift,* May 29, 1905.

8. The American Medical Association was organized when a convention, representing all the organized medical societies, "resolved itself into the American Medical Association." This action was taken, May 7, 1847.

9. There was a Red Cross organization in the United States as far back as 1869. It was incorporated in 1881 and again in 1893 and in 1900. In 1904 the American Red Cross was entirely reorganized, and Jan. 15, 1905, Congress passed an act incorporating the present American National Red Cross and establishing the conditions that should shape its career. The incorporation papers for the Red Cross organization in 1881 were filed, October 7, at 3 o'clock.

CONTRACT SURGEONS

To the Editor:—Kindly give me some information about contract surgeons in our Army. Do salaries vary or are all paid the same amount? What is the salary? Would a specialist be assigned to his specialty in this contract service, or to any kind of work where he would be needed?

A. G.

Answer.—According to the Act of Feb. 2, 1901: "In emergencies the Surgeon-General of the Army, with the approval of the Secretary of War, may appoint as many contract surgeons as may be necessary, at a compensation not to exceed $150 per month." According to the Manual for the Medical Department, contracts are entered into only by the Surgeon-General or by his authority. They are either general or special. A general contract obligates the contract surgeon to take station and change station as ordered. He is furnished quarters and receives pay as stipulated in the contract, and the travel, fuel and light allowances of a first lieutenant. He is expected to give his entire time to the public service. If the exigency requiring the employment of a contract surgeon is likely to be temporary, contracts are made for a term of three months or less; if its longer continuance is probable, the term is one year. In either event, it is subject to annulment when the services of the physician are no longer required.

Special contracts are for local service only at stations designated where the amount of service called for is not sufficient to warrant the assignment of a medical officer. No travel is required under such contracts. The physician contracted with is not expected to take station at the post or to give up his private practice except so far as it is necessary to do so in order to carry out his public duties. He is not furnished quarters or other allowances.

CONTRIBUTIONS FOR BELGIAN AND FRENCH PHYSICIANS

To the Editor:—A number of times recently I have noticed requests for surgical instruments to be donated and sent to various fields of usefulness. A woman whose husband was a prominent physician here up to the time of his death wishes to know where to send the balance of his instruments that they may be of the most service. They are in good condition, are for the greater part of the old style ebony handle days, are mostly bone amputating sets, etc., and include an old fashioned light wooden splint outfit.

C. W. Ellyson, M.D., Waterloo, Iowa.

Answer.—The instruments may be sent to Dr. W. W. Keen, 1729 Chestnut Street, Philadelphia. Dr. Keen has asked those who have surgical instruments to spare to donate them to the civilian physicians of Belgium and France. Even old fashioned instruments can be disinfected, and they will prove of the greatest use when these physicians return to their devastated homes.

Scarcity of Mercury in Denmark.—S. Lomholt writes to the *Ugeskrift for Læger* of Copenhagen to warn of the necessity for strict economy in the use of mercury. He says that most unexpectedly it has been found that the supply is cut off by the new American blockade policy, just when the supplies on hand were unusually low. He doubts whether the condition can be much improved, as mercury is used in the manufacture of munitions. No one seems to have foreseen the possibility of a scarcity of mercury. He suggests that mercury be given in treatment of syphilis by intravenous injection instead of the wasteful inunction method, with which only about 1 per cent. is absorbed.

Book Notices

Fresh-Water Biology. By Henry Baldwin Ward, Ph.D., Professor of Zoology in the University of Illinois, and George Chandler Whipple, Professor of Sanitary Engineering in Harvard University. With the Collaboration of a Staff of Specialists. Cloth. Price, $6. Pp. 1111, with 1,547 illustrations. New York: John Wiley & Sons, 1918.

Fresh-water biology in North America has hitherto been a comparatively untilled field, as the earliest records of biologic research date back scarcely fifty years. The studies of Ward and Whipple, prepared with the aid of twenty-five skilled collaborators and recently published for textbook and reference use, give the literature an auspicious start. Each chapter concerns a simple group of organisms, whose life history is given in condensed form. Especially valuable for the student are the descriptions of the various methods of collecting, preserving and studying the organisms of the different groups. The first few chapters discuss general biologic factors. This discussion, however, is not confined to the introductory pages, as a later chapter on Rotifera includes an admirable description of the life processes that apply to all groups of many-celled organisms. Fresh-water life is roughly divided into two groups—plant and animal organisms. The plant group comprises the bacteria, or lowest type in water, the higher plants, and the omnipresent algae, the last being exhaustively treated. Classified at even greater length are the twelve animal groups, ranging from the Protozoa and the sponges up to the Mollusca and the aquatic vertebrates. The final chapter is an interesting study of those technical and sanitary problems that vex municipal health authorities and sanitary engineers. Here Whipple considers fresh water as a medium for conveying diseases either indirectly, through the breeding of mosquitoes, as in yellow fever and malaria, or directly, through the infection of drinking water and the aquatic food supply, as in typhoid, Asiatic cholera and dysentery. The chapter furnishes a wealth of practical information on such subjects as the elimination of bacteria in water by means of filtration, aeration and the use of chemicals; the treatment of sewage; the disinfection of swimming pools, and the various methods of killing algae and animal organisms and of checking their growth in reservoirs and standpipes.

Surgery and Diseases of the Mouth and Jaws. A Practical Treatise on the Surgery and Diseases of the Mouth and Allied Structures. By Vilray Papin Blair, A.M., M.D., F.A.C.S., Professor of Oral Surgery in the Washington University Dental School. Third Edition, Revised so as to Incorporate the Latest War Data Concerning Gunshot Injuries of the Face and Jaws. Compiled by the Section of Surgery of the Head, Subsection of Plastic and Oral Surgery, Office of the Surgeon-General of the Army, Washington, D. C. Cloth. Price, $6. Pp. 733, with 460 illustrations. St. Louis: C. V. Mosby Company, 1917.

The enormous number of injuries in battle involving the mouth parts, with a large percentage of jaw fractures, which require the combined services of both the general and the oral surgeon, caused the Surgeon-General to establish a special division composed of general surgeons especially trained in plastic operations on the face and neck, and dental surgeons especially trained in the treatment of fractures and other jaw injuries. As chief of this division, Major Blair saw the need of a book covering this particular field, and therefore incorporated in this edition of his book the latest data relative to gunshot injuries of the oral region, thus correlating the mass of recent literature on this subject. The book reflects close association with the rapid changes in methods that have occurred since the opening of the war, and merits careful reading by every member of the Medical and Dental Corps. The chapters on plastics of the face and neck, fractures of the jaws, and anesthesia are exceptionally well presented and fully illustrated. The chapter on plastics occupies thirty-one pages and has thirty-five illustrations, many from cases in the author's practice; the chapter on fractures of the jaws occupies sixty pages and contains fifty-nine illustrations. The book is not confined to war surgery; it covers the entire field of oral surgery. The more important chapter titles include cleft palate, which is fully presented and illustrated, the regional anatomy, infections, hemorrhage, shock, wounds, ankylosis of the temporomandibular joint, fractures of the nasal bones and deformities of the nose, infections in and adjacent to the teeth, chronic infections of the mouth, diseases of the maxillary sinus, tumors of the mouth and jaws, affections of the salivary glands, tuberculosis of the cervical lymphatics, diseases involving the pharynx, motor derangements, and tic douloureux.

Knowledge of Nature and Duration of Disease is Privileged

(Lombard vs. Columbia National Life Insurance Co. (Utah), 168 Pac. R. 269)

The Supreme Court of Utah holds that there was no error, in this section on a life insurance policy, in excluding, as privileged, the testimony of a physician, who attended the insured, as to the nature and duration of the disease of which the latter died. The court says that, under the Utah statute, the question as to how or when the physician acquired the information sought to be proved is immaterial. If it was information acquired while attending the patient which was necessary to enable the physician to prescribe or to act for the patient, then, under the statute, it would be privileged. The facts proposed to be proved in this case were that the insured died of cancer of the stomach and liver; that, after the physician had ascertained the fact of the disease, he considered it due the afflicted man to tell him of the seriousness of his condition and that it was incurable, and that after that the man wept and then voluntarily told the physician, without any further inquiry, that he had been sick for two years suffering with his stomach and pains in his back. Under the authorities the question of the admissibility or inadmissibility of the foregoing proposed testimony, under statutes similar to that of Utah, is not easily determined. And this court has determined, in common with many other authorities, that not all communications made to the attending physician are excluded under the provisions of the statute. But the fact that the insured was afflicted with cancer could become known to the physician only while attending the patient, and was, of course, necessary to enable him to prescribe for him. The knowledge that the patient died of that disease would also be a matter the physician would ascertain from his treatment of the patient. Clearly such facts would be privileged as being information acquired while attending the patient. The further fact proposed to be proved by the physician, as to the statement made by the insured, would not, standing alone, without other aid or explanation, prove or tend to prove the insured died of cancer, or prove the nature of the disease that caused his death. In addition, it must, the court thinks, be accepted as a fact, universally recognized not only by the medical profession but by every one, that a physician, in attending or prescribing for a patient, of necessity ought to know and does know, and does ascertain for that purpose from his patient, the duration of the disease, which, of necessity, must aid him in determining the nature of the treatment to be given, the patient's strength or ability to undergo surgical operations or take other severe treatment, and the likelihood of such treatment proving beneficial or proving fatal, as it did in this case. Such would seem to be accepted as a matter of common everyday knowledge, and, as such, recognized and enforced by the courts. The fact as to whether the disease to be treated is chronic or acute—in other words, its duration—surely is a part of the information that every physician would want to know and would need to know in the intelligent discharge of his duties, to enable him to prescribe for and treat his patient. Whether the physician acquired the information, as stated above, from voluntary statements of the patient, or whether it was acquired from investigation or inquiry on his part, it would, nevertheless, be included within the information privileged under the statute.

2. **New Operation for Cystocele.**—The technic offered by Rawls is an extraperitoneal operation with a free mobilization of the bladder and its pillars. A small volsellum forceps is applied to the mucous membrane of the anterior vaginal wall about 1 cm. above the cervix and another forceps about 1 cm. below the external urethral orifice. Between these forceps a vertical incision is made through the mucosa and superficially into the underlying tissues. The incision is carefully carried forward until, in the midportion, the bladder can be demonstrated by blunt dissection. This blunt dissection is continued downward until the cervical attachment of the bladder pillars and the so-called uterovesical ligaments are demonstrated. The latter is cut with scissors, keeping well in midline to avoid severing any of the cervical attachments of the bladder pillars. The bladder is separated by blunt dissection, from the cervix upward to the peritoneal reflection and laterally well out to either side, and from the underlying pillars upward to the urethra and well out on either side. If there is a urethrocele, the dissection is carried up to the external urethral orifice. When the bladder is well mobilized, the bladder pillars are dissected from the underlying vaginal mucosa. The bladder and its lateral true ligaments are now freely mobilized and the latter are overlapped from side to side by transverse mattress sutures of medium kangaroo tendon, at the level of the internal os one or two sutures enter the cervical tissue. These sutures prevent anteroposterior shortening of the anterior wall of the vagina and draw the underlying fascia smoothly under the overlapping fascia. In addition the cervical suture reattaches the fascia to its original place on the cervix and forms a shelf on which the bladder rests. After the mattress sutures are tied, the free edge of the overlapping fascia is sutured, by interrupted sutures of fine kangaroo tendon, to the underlapped fascia. The paper-thin vaginal mucosa flap, caused by dissection, is now excised for a short distance on either side. Its edges are approximated in midline by interrupted suture of ten-day chromic catgut. To prevent a dead space between the fascia and mucosa a vaginal pack of iodoform gauze is used and is removed the fourth day after operation. The method is said to be applicable to all forms of cystocele, but when there is a complete prolapse of the uterus, other methods must be used in addition, to relieve the injury to the posterior segment of the "holding apparatus" and the injury to the supporting apparatus.

4. **Effect of Desiccated Placenta on Lactation.**—The results of McNeile's investigation do not warrant any definite conclusions. In the patients fed desiccated placenta there was apparently some change in the chemical composition of the milk during the first eleven days postpartum. The most marked change was an increase in the percentage of lactose and this was accompanied by a slight increase in the percentage of protein, and a slight decrease in the percentage of fat. There was no deficiency in the amount of milk in any of the cases receiving desiccated placenta, but the reverse was true in the cases which did not receive this agent. There was apparently a slight decrease in the initial loss of weight in the infants of mothers receiving the desiccated placenta, over those whose mothers did not receive it. At the end of eleven days the babies whose mothers received the agent were about 4 ounces heavier than those that did not.

7. **Ulceration of Vulva.**—Schiller's case was one of acute ulceration of the vulva, which was preceded and accompanied by chills and fever, burning and general malaise, acute ulcerations which had all the characteristics of ulcer mollia or soft chancre. The presence of a peculiar form of bacilli in all smears, the absence of all other microbes and the rather unusual clinical picture show this was not a case of one of the known and well studied and recognized ulcerative processes of the vulva, but with a lesion not previously described.

20 *Prognosis and Treatment of Tuberculous Lesions of Larynx. J. Dworetzky, Otisville, N. Y.—p. 1.
21 *Tobacco and Throat Complications in Pulmonary Tuberculosis. W. S. Duboff, Edgewater, Colo.—p. 21.
22 *Effect of Inhalation of Cigaret Smoke on Lungs. G. B. Webb. —p. 25.
23 *Typhoid Bacteremia During Course of Miliary Tuberculosis. A. Bloomfield, Baltimore.—p. 28.
24 Control of Careless Consumptive. D. R. Lyman, Wallingford, Conn.—p. 36.

20. **Treatment of Tuberculous Lesions of Larynx.**—Summarizing the treatment of tuberculosis of the larynx, Dworetzky says that the most important measures are: (1) the local and general prophylaxis; (2) the general treatment; (3) vocal rest in selected cases; (4) topical applications with a solution of iodin in increasing strengths.

21. **Tobacco and Throat Complications in Tuberculosis.**—A statistical study made by Duboff to determine the influence of tobacco as an etiologic factor in laryngeal involvement during the course of pulmonary tuberculosis. One thousand histories of tuberculous cases were studied. Of the 1,000 cases there were 793 males and 207 females (3.8-1). There were 299 throat cases (29.9 per cent.). Among the 793 men there were 240 throat cases (30 per cent.) and 368 (46 per cent.) light, moderate or excessive smokers. Of these 368 smokers 133 (36.1 per cent.) developed "throats," while among 425 nonsmokers there were 107, or 25.2 per cent. Among 207 women 59 had throat involvement (29 per cent.). Duboff concludes therefore that throat complications are probably no more frequent in tobacco users than in those who use no tobacco. Laryngitis, whether of specific character or not, is as equally common among women as among men in the course of pulmonary tuberculosis. In an equal number of men and women with pulmonary tuberculosis, the majority of throat involvements will be associated with a negative tobacco history. Tobacco obviously does not predispose to laryngeal complications.

22. **Effect of Cigaret Smoke on Lungs.**—There is no doubt in Webb's mind that the inhalation of cigaret smoke produces ronchi. The majority of cigaret smokers examined by him revealed the presence of bronchial ronchi, whereas the majority of nonsmokers, of pipe smokers and of cigar smokers do not show such evidence. Bull Durham causes more irritation than other tobaccos. In addition to ronchi, medium and coarse râles were observed in many heavy cigaret smokers. These râles would usually disappear after several coughs. Occasionally a very quiet vesicular murmur was observed. Regarding the soldiers who were found tuberculous and deemed unfit for service by Webb and his co-workers on War Department tuberculosis boards, the table indicates that a somewhat larger percentage of nonsmokers were discharged than smokers. Adding to the nonsmokers those who do not inhale and who do not show evidence of the production of ronchi, namely, the pipe and cigar smokers, the observation was made than 30 per cent. of those discharged, on account of pulmonary tuberculosis did not inhale cigarets. These studies would at least suggest that the inhalation of the smoke of cigarets does not aid in the outbreak of pulmonary tuberculosis.

23. **Typhoid Bacteremia in Miliary Tuberculosis.**—Two cases are reported by Bloomfield which are probably to be looked on as cases of miliary tuberculosis in whom an accidental invasion of the blood with typhoid bacilli occurred. A previous carrier state would most adequately explain the source of the organisms.

25. **Effect of Trauma on Laryngeal Nerves.**—From time to time, a complete or partial paralysis of the vocal cords is seen following thyroidectomy. The purpose of this research was to determine if possible the cause of such paralysis. The method of experimentation consisted in traumatizing the laryngeal nerves in a manner similar to that which could occur in an operation and subsequently to study the function of the vocal cords. It was seen that section of the recurrent laryngeal nerve produces complete paralysis of the vocal cord of the corresponding side which in all probability will be permanent. Ligation of the recurrent laryngeal nerve with linen, chromic catgut or plain catgut produces complete and probably permanent paralysis of the vocal cord of the corresponding side. Stretching the recurrent laryngeal nerves acutely in a manner similar but of longer duration and intensity than occurs in operation does not impair the function of the vocal cord. Stretching the recurrent laryngeal nerves for a long period, as over muscles, impairs the function of the vocal cords, but the impairment is probably due to the operative trauma and not to the stretching. Pinching the recurrent laryngeal nerves with a hemostat in a manner similar to that which may occur in an operation, produces temporary paralysis of the vocal cords. Restoration of function always occurs, the length of time necessary for restoration depending on the anatomic point at which the nerve was crushed. The time found necessary for complete regeneration of the nerve when injured in the areas usually traumatized by operation varies between thirty and sixty days. Exploration of the recurrent laryngeal nerves produces an effect on the vocal cords depending on the amount of trauma to which the nerves are subjected. Careful dissection will probably not produce any effect; the paralyses noted were probably due to pinching and other traumatic procedures.

26. **Pneumococcus Peritonitis.**—Syms maintains that idiopathic peritonitis does occur. Pneumococcus peritonitis is a rare disease, particularly affecting girls under 15 years of age. It may occur (1) as a single lesion, that is, alone; (2) as a sequel to some other site of infection, as the lung, pleura, etc.; (3) it may be followed by invasion of other localities, lung, pleura, etc.; (4) it may be a local manifestation of a general septicemia. Syms suggests that probably it is always that. Pneumococcus peritonitis is found in two forms: (1) the diffuse; (2) the encysted. These forms may represent different types or varieties of the disease or they may represent different stages of the disease. This is yet to be demonstrated. When the peritonitis is encysted the prognosis is good, spontaneous recovery may take place in one of several ways. Operation results in a high percentage of recoveries (86 per cent.). When the peritonitis is diffuse the prognosis is bad—death is the rule. Operation results in very high mortality (86 per cent.; in some series 100 per cent.). We recognize a symptom syndrome which should make diagnosis reasonably certain in typical cases. Operation should not be performed in the diffuse form. Operation should always be performed in the encysted form.

32. **Osseous Cysts and Giant-Cell Sarcoma.**—Platou reports cases showing that ostitis fibrosa with formation of tumor is not very rare. It occurs most often in young persons, but may also be found in persons of 50 to 60. Trauma appears in many cases to be an etiologic factor, although we are unable to explain how it can cause the disease or influence its genesis. The course of the disease is chronic with comparatively slight symptoms, rheumatic pains, and a slow swelling of the affected bone. The general health is good. Spontaneous fracture or bending of the bones may occur. The roentgenogram is often typical, but sometimes it is impossible to decide whether the diagnosis might not with equal correctness be given as sarcoma. The treatment is

exclusively surgical, all diseased tissue must be carefully removed, albeit with an obligation to be as conservative as possible. When the bone is opened the cavity is found to be more or less filled with a brownish red or sometimes yellowish, crumbling tumor tissue. The borderline is, as a rule, sharply drawn, although the same tissue may be found outside the periosteum. Under the microscope the destruction of the bone is seen to take place in a connective tissue with few cells, that is, fibrous marrow. Formation of new bone is also seen. The tumor-like tissue is built up partly by very polymorphous cells with numerous and uncommonly large giant cells, partly from a fibrous tissue with few cells. Mucous tissue with softening and formation of cysts also occurs. It is sometimes difficult to decide that the diagnosis is not sarcoma. The disease is benign even when the periosteum is perforated.

43. **Pus Corpuscles in Infant Stool.**—For two years Zahorsky has made a study of the infant stool for the presence or absence of pus corpuscles. He has reached the conclusion that a pus index of more than 10 indicates an infection of the intestinal mucous membrane; that an infectious process of some solitary follicles (or some other part of the mucous membrane) exists in many cases which are diagnosticated fermentative diarrhea. The so-called summer diarrhea is generally an infectious process.

2. **New Opera**ead. When present in nonmedicated cases. Rawls is an ex sed bodily condition was also present. The tion of the bladd taken, therefore, as a sign of disease. This is applied to the study of *392 cases in* which the red streak was found present. In 310 of the cases—79 per cent. of them—a purulent condition in some part of the body was found; *the remaining eighty-two* cases being nonpurulent disease conditions of the body. For this reason, in nonmedicated cases, when the red streak is constantly present when tested for, the first thought is of pus. If thorough search excludes a pus focus, there is present infection, or a disturbance within the domain of endocrinology—a disturbance in the balance of the internal secretions—and manifested by lymphatism, hyperthyroidism, hyperplastic thymus, diabetes mellitus, etc. The relation of the red streak to the thyroid secretion has been shown in cases of mild myxedema, in which the normal reflex diastole of the face to stroking was absent. In these cases, on administering to them thyroid extract, the red streak appeared. Digitalis medication can also lengthen the normal reflex diastole of the peripheral blood vessels, and so give the red streak; likewise, pilocarpin. Functional heart cases—so-called nervous heart—is found associated with the red streak. Twelve cases were met with and tested. All gave the red streak. In four of these cases, the phenomenon of partial fading and intensifying of the streak, that is, active *systole and diastole of the peripheral* vessels, was visible. A practical illustration of the value of the red streak in diagnosis is furnished in focal infection. In several cases of apical abscesses, a *positive diagnosis* was *made from* the presence of the red streak associated with slight tenderness to pressure over the root that had at a previous period been opened and treated. The diagnosis in these cases of apical abscess was confirmed by roentgenogram or by evidence furnished on root extraction.

60 The Ballenger "Sealed-in" Abortive Treatment for Gonorrhea. A. B. James.—p. 12.

56. **Spur-Like Formations of Bone Following Amputation.**—In the routine roentgen-ray examination of amputation stumps following on war wounds, Morgan has seen, in the majority of cases, a shadow projecting from one or other (usually the internal or posterior) border of the bone *shaft* near its extremity. In one case this represents but a small spicule; in another, a large thick spur; in a third, the impression given has been of the presence of a "wing" of bone. As a rule these project in an upward direction. They are frequently the source of considerable pain and discomfort, and are responsible for the persistence of a discharging sinus. Their presence, consequently, often necessitates a reamputation. Occasionally they recur following this operation. The presence of these spurs is one of the principal causes necessitating the reamputation of a stump. These operations have been very frequent during the past three years. It is obviously a matter of great practical importance, therefore, to prevent the formation of these spurs in the first place. Can this be done? Morgan agrees with Steiger that satisfactory results can be obtained by any of *the three methods, provided* (1) that the operation is properly performed; (2) that primary union occurs, and (3) that the stump is at an early stage accustomed to bear weight, and can thus adapt itself rapidly to its new functions.

57. **Infectious Ulceromembranous Stomatitis and Gingivitis.**—One thousand men were examined by Bowman *in camp*, both clinically and bacteriologically, to learn, if possible, the number of men who cleaned their teeth carefully and the number of men who did *not*, and the number of men in each of these groups showing Vincent's organisms present in numbers sufficient to be diagnostic; also the numbers of cases of clinically infectious gingivitis in each of these groups. The men examined may be divided into two classes: those with

clean and those with unclean teeth. In the first group there were 816 men, and 314, or 38.4 per cent., of these showed Vincent's organisms present, but very few in number; 20, or 6.4 per cent., showed large number of spirochetes and fusiform bacilli, and were, clinically, positive cases. In the second group there were 184 men, and 139, or 75.6 per cent., of these showed a few Vincent's organisms present; while in 59, or 32 per cent., the organisms were present in preponderating numbers, and these cases were all clinically positive. Thus it is shown that not only are Vincent's organisms much more prevalent in mouths in cases in which the teeth are not cared for, but clinically infectious gingivitis is also much more prevalent, and corresponds practically with the bacteriologic findings. "Trench mouth" may be described as an infectious disease of the mucous membranes of the mouth due to a spirochete and fusiform bacillus (Vincent's organisms), causing severe inflammation which may progress to ulceration, accompanied by constitutional disturbances, such as fever, gastric disorder, loss of weight, and marked depression.

58. **Streptococci Recovered from Sick and Wounded Soldiers.**—A series of cases examined by Malone and Rhea showed that in direct injuries of the knee joint and indirect injuries with fracture of the femur or tibia, streptococci are usually found before the fifth day. In secondary infections where there has been no fracture into the joint, streptococci are recovered from the knee-joint fluid from the eighth to the twentieth day. In thoracic injuries with infected hemothorax these organisms are found between the seventh and fourteenth day after injury. Nonhemolytic streptococci are an uncommon cause of the surgical complications of wounds, except in cases of hemothorax, in cases in which they are usually of the types found normally in the respiratory tract. *Streptococcus pyogenes* is the type most commonly found in infected wounds. It is also the most pathogenic. The evidence to support the latter view is as follows: Of eight cases of infection in the knee joint, five developed secondary abscesses in the thigh or calf. *Streptococcus pyogenes* was found in the knee fluid and abscess in each of these cases. Of three cases of infection in the knee joint which required amputation, two contained pyogenes. Four cases of infected hemothorax ended fatally; three of these were due to *Streptococcus pyogenes*. This organism was recovered from the three cases of infected open wounds of the soft tissues, which were complicated by an infected hematoma or abscess. There was only one serious case of infection in the knee joint that was not caused by *Streptococcus pyogenes*. There was only one mild case of an infected knee joint in which pyogenes was the causative agent, and this case had the advantage of very early surgical treatment. So far as streptococci are concerned in the surgical complications of wounds of war, the type which is most common, and leads to the most serious results, is the same as is met with in civil surgery.

67 Traumatic Rupture of Jejunum. L. B. Robertson.—p. 235.

64. **After-History of War Nephritis.**—Fifty patients were examined by the authors. Almost all cases show after a period of three months a trace of albumin, a few granular and hyaline casts, red blood cells, and pus. The chlorids and urea are about normal. Nocturnal micturition is present in nearly 40 per cent. of the cases, and there is probably a slightly greater amount passed during the night, between 8 p. m. and 8 a. m., than during the day. Many still complain of dyspnea, slight headache, pains across the lower part of the back, and a few develop slight transient return of edema. They are usually very well nourished, and not anemic; in fact there was usually a striking absence of the pale countenance so common in the ordinary nephritis of civil life. The blood pressure is usually normal, and there is no enlargement of the heart. Structural retinal changes are rare, having been seen in only one of the authors' series. A striking feature has been the fact that in over half the cases there has been at the onset acute catarrh of some part of the respiratory passage, most frequently a bronchitis, which was usually regarded as simply a "cold."

79. **War Deafness and Its Prevention.**—The tests reported by Guild were made by means of the tambour method. The first thing noticed in studying the results is the division of the preventives into two distinct groups on the basis of the efficiency in stopping the force of the detonation waves. The ones that permitted the detonations to cause large movements of the tambour are the same ones that permitted the greatest injuries to the middle ears of animals. To these latter is added here the Elliott "Swimmer," which was not tested on animals. It is better than the Elliott protector, but would certainly permit positive damage to the ears under conditions similar to those used with the animals. On the other hand, the Scientific Ear Drum Protector "Tommy," which the middle ear conditions indicated as the best of the devices tested, has continued to be the device of choice. The Mallock-Armstrong Ear Defender is not quite so effective with these tests, but continues to be in the same group. The glycerin and petrolatum soaked cotton plugs have given better results here than in the animal tests; they are the only preventives that have not remained in the same relative positions in the order of efficiency as tested by the two methods. The Wilson-Michelson device is relatively and absolutely more effective with the heavier waves.

81. **Bacteriology of Ozena.**—A summary of the authors' study of 100 cases shows that the group of organisms known as the *B. mucosus-capsulatus* (Friedländer's bacillus, Abel's bacillus) is preponderant and may be pathognomonic in cases

in the animal inoculated, but it is impossible to reproduce the disease from this animal in others. With a still finer filter, the virus induces merely cachexia without actual rabies. Chemical substances in solution, on the other hand, pass through the filters regardless of the porosity. The rabies virus therefore, in regard to the filters, behaves differently from both bacteria and chemicals.

The rabies virus behaves paradoxically also in centrifugation. This has no effect on a chemical solution, but it does have a very slight effect on rabies virus; the virus very slowly leaves the upper layers of the fluid. In short, the rabies virus, filterable and diffusible, seems to offer a connecting link between the visible microbes, which represent the lower limit of the vegetable kingdom, and the diastases, that is, the colloidal substances which may be regarded as at the highest limit of the inorganic bodies. It is thus a transitional form between the visible microbes and the colloids.

21. **Drilling the Prostate.**—Luys describes the simple technic with which, under direct visual inspection, he destroys in the interior of the hypertrophied prostate the obstacles which prevent the free course of the urine. There may be a kind of dike between the bladder and the urethra, or the two enlarged lobes may be stuck together. It is better to bore a passage in several sittings, instead of trying to accomplish it all at once. From three to six sittings are usually sufficient, at intervals of a week. If the actual cautery starts bleeding, electrocoagulation will arrest it at once.

Bulletins de la Société Médicale des Hôpitaux, Paris

28 *The Bacterial Flora of War Wounds. Plisson, L. Ramond and C. Vergelot.—p. *1295*; (id.) *1302.*

22. **Spirochetosis Without Jaundice.**—Favre and Mathieu relate that in seven men recently in their ambulance spirochetes were found constantly in their urine, up to six weeks in one and for three months in two. All looked thin and pale and complained of vague pains, and were incapable of work; over the cheek bones the skin was red but elsewhere was brownish. One man had a hydrarthrosis resistant to the salicylates; another succumbed to severe nephritis. The congestion of the skin was so marked in one case that scarlet fever was diagnosed at first. The spirocheturia was constant at first but became intermittent later.

26. **Paralysis of the Pneumogastric Nerve.** — Vernet describes how certain war wounds have entailed paralysis of the pneumogastric system, manifested by disturbances in sensibility, in salivation, and in the breathing. A pseudo-asthma follows the paralysis of the sensory fibers of the pneumogastric in the lungs, while dyspnea on exertion results from irritation of these fibers. Other manifestations are described which throw new light on the part played by the pneumogastric in the pathology of the lungs in general.

27. **The Sympathetic Syndrome.**—Ramond has had a certain number of men in his service presenting a set of symptoms which classed them in a group as suffering from the results of derangement in the functioning of the sympathetic nervous system. The symptoms are essentially vasomotor, cardiac and secretory, with sometimes respiratory, dyspeptic and mental disturbance and tremor. They occur in attacks and these may be restricted to one or more of the symptoms and to some special region. Some of the symptoms can be explained by exaggerated irritability of the nerve, others by a state of inhibition, one part of the nerve functioning to excess and another part inadequately functioning. The men thus affected had been classed as having some heart disease, on account of their tachycardia, or as alcoholics, on account of their tremor, their emotional instability, their puffy faces. Others as dyspeptics, because their disturbances manifested themselves after eating. But they are most likely to be classed as having exophthalmic goiter. An inherited taint is evident in many cases. An infection or alcohol is liable to bring on especially severe attacks. It is possible that some defective internal secretion may be the primal cause of this sympathetic syndrome.

28. **The Flora of War Wounds.**—Plisson, Ramond and Vergelot report the bacteriologic findings in 428 personal examinations of the wounds of 186 soldiers, and compare with their findings those of Carrel, Tissier, Wright and other workers in this new close collaboration between the surgeon and the bacteriologist. All agree that the cultures do not become positive until after the fourth or fifth hour, often not until after the tenth or even later. Positive smears were obtained only in 14 of 75 wounded examined, before any intervention, between the fourth and forty-eighth hours; anaerobic cultures were positive in 13 and aerobic in 32. All war wounds contain germs from the first, but they are few and lie close to the foreign bodies at first. The perfringens was the only anaerobe they succeeded in cultivating from the wounds with the simple technic used. It was alone in 8 per cent. of the cases. Association of aerobes and anaerobes was evident in 60 per cent. of the cases. They describe the various features observed in wounds with anaerobes and aerobes and with and without the streptococcus. The presence of anaerobes does not necessarily entail putrid transformation; there were only 6 cases of gangrene among the 75 men. The perfringens persisted apparently harmless until after the tenth day in 22 cases, and in 3 beyond the fifteenth, but such cases show the possibility of tardy gangrene. The primary suture proved a success, notwithstanding the presence of the streptococcus, in 24 cases, associated with anaerobes in 13; the presence of the colon bacillus in 9; the enterococcus in 8; diplococci in 5, and the proteus in 3.

28. **Practical Application of Bacteriologic Findings in Wounds.**—The bacteria found in wounds are not inevitably pathogenic, but the streptococcus almost invariably confers a special and malignant course on the wound. Associated with anaerobes, rapid gas gangrene is liable. Hence the task of the bacteriologist is mainly to determine whether the streptococcus is present or not. Smears are usually unreliable and the ordinary culture technics often fail to reveal the streptococcus. The writers' experience indicates that with ordinary bouillon, containing some albumin, the streptococcus can be shown up in six hours. They used four parts bouillon to one part *albumine à la soude de Sacquépée.* But even with this, the findings came too late to be of any assistance to the surgeon in determining whether it is safe to suture at once a recent wound. The surgeon is the sole judge of what is best to be done, and this is determined by the more or less complete clearing out of all devitalized tissue. But the bacteriologist demands the opening up of every suture when he finds that the streptococcus is present. With other germs the surgeon is free to maintain or open up the suture as the clinical course suggests.

The bacteriologic findings should also be the criterion for the proper moment when no longer recent wounds, under progressive sterilization, are ready to be sutured. Carrel's rule is to suture when two consecutive examinations, at one or two days' interval, show only one microbe to four or five microscopic fields. For deep wounds, he demands several examinations in the course of four or five days. The streptococcus, however, even in small numbers, formally contraindicates suturing. Relying on these rules they applied primary suture in 90 war wounds, in less than twenty-four hours, with complete success in 60 of the cases. In 22 cases the wound was reopened for clinical or bacteriologic reasons. In all but 10 in this group the streptococcus was present, associated with the perfringens in 7; in one case the staphyococcus was associated with anaerobes, and in 6 the perfringens accompanied various germs. In 5 of the cases a primary total suture and in 3 a partial suture separated when the threads were withdrawn the tenth day; the streptococcus was present in 3 in this group. The others had anaerobes except in one case in which the staphylococcus alone seemed responsible. The laboratory findings conferred a confidence, even amounting to audacity, which was justified by the 66 per cent. of completely successful primary sutures.

29 *Roentgenoscopic Outlining of Ventricles. H. Vaquez and E. Bordet.—p. 113.
30 High Blood Pressure with Nonvalvular Heart Disturbance. P. Merklen.—p. 116.
31 *Protracted Parameningococcus Septicemia. H. Aimé and H. Chéné.—p. 118.
32 Psoriasiform Dermatitis. H. Gougerot.—p. 121.
33 Extraction of Shell Scrap in Lumen of Axillary Artery. M. Patel.—p. 125.

29. **Detection of Hypertrophy of the Ventricle.**—Vaquez and Bordet recall that the left ventricle does not form much of the front aspect of the heart, its position being mostly deep in the mediastinum. In order to detect slight, incipient hypertrophy we must ascertain the depth to which it reaches backward, and they have worked out a roentgen technic which permits this. The depth is calculated by superposed triangles, like the formulas for locating a foreign body in the depths of the tissues. The tube is centered at the apex and the edge of its profile is marked on the glass. A footrule is then placed on the screen and the tube is moved toward the observer's left until the normal rays pass through a point 10 cm. distant from the first mark, and the new edge of the profile is marked on the screen. The number of millimeters between the two marks represents the depth to which the ventricle has developed backward. They have the subject stand, resting his chin on the screen. This immobilizes him enough. The whole procedure is simple and brief, while experience is confirming its reliability in the early diagnosis of hypertrophy of the ventricle. The index in normal conditions ranges from 7 to 14 mm. With various forms of heart disease they found the index 18, 20, 25 or 40 mm.

31. **Tardy Meningitis.**—Aimé and Chéné urge the importance of early lumbar puncture in dubious cases without waiting for actual meningitis to develop. This gave the clue and permitted effectual treatment in a case described which otherwise would not have been cleared up in time. The main symptoms were those of a septicemia dragging along for a month with intermittent attacks simulating those of malaria. Finally symptoms suggesting meningitis developed, and a few diplococci were found. Diplococcus septicemia is rare; only twelve cases have been published to date, they say, including Marie's three. Under serotherapy the man was discharged cured nearly four months after the first symptoms had attracted attention: fever, pains in the legs, headache and a transient papulous eruption. The attacks with chill, high fever, eruption and pains in the joint returned irregularly. Nine intraspinal injections of antiserum were made in the course of three weeks, and the antiserum was injected subcutaneously a few times.

34 *Transfusion of Citrated Blood. E. Hédon.—p. 57; E. Jeanbrau.—p. 58.
35 *Treatment of Ischemic Contracture. J. Luzoir.—p. 62.

34. **Transfusion of Citrated Blood.**—Hédon gives the history of this method of transfusion, awarding the priority to Agote of Buenos Aires, as Hustin's technic, published the year before, differs from simple citrating of the blood. Hustin injected blood diluted with a solution of sugar and citrate.

Jeanbrau gives numerous illustrations of his simplified technic for the purpose, which he is applying as a routine measure in severe posthemorrhagic anemia with or without shock, carbon monoxid poisoning, uncontrollable hemorrhage, hemophilia, pernicious anemia and certain cases of shock. His research has confirmed that the usual dose of citrate dissolved in blood has no hemolytic action. In Hédon's tests the citrated blood kept on ice for ninety-two hours up to eight days seemed to be fully as effectual in resuscitating exsanguinated animals. Jeanbrau adds that the citrate is not an aphysiologic or antiphysiologic substance; the mammalian organism produces a physiologically citrated fluid: milk. Experience has shown further that transfusion of citrated blood does not expose to secondary hemorrhages. In short, he concludes, the transfusion of citrated venous blood is as effectual as the direct vein-artery technic while the facility, rapidity and security of the method are peculiarly valuable for the otherwise moribund exsanguinated wounded.

35. **Treatment of Ischemic Contracture.**—Luzoir presents arguments and recently acquired data which sustain the view that mechanical and orthopedic rather than surgical measures are the best treatment for Volkmann's disease.

Correspondenz-Blatt für Schweizer Aerzte, Basel

Feb. 2, 1918, **48**, No. 5

36 *Hill Climbing as Therapeutic Measure. (Ueber Terrainkuren.) A. Jaquet.—p. 129.

36. **Therapeutic Hill Climbing.**—Jaquet is enthusiastic over the results to be obtained with Oertel's system of graduated hill climbing exercises in treatment of disease of the cardiovascular system. When done with the necessary caution and under the constant supervision of an experienced physician, there is no need to fear injury of the heart, as the course can be stopped at the first sign of trouble. The success obtained with it in many cases was the most gratifying he has ever had in the treatment of disease of the circulatory apparatus. He explains how the bending of the legs in climbing has a special aspirating action on the blood in the veins of the legs, far beyond that with walking on a level, or with gymnastic exercises as the latter are done only for a few minutes at a time. The aspirating action is enhanced by the deeper breaths taken in climbing. Any tendency to dilatation of the ventricle must be scrupulously avoided. He begins by having the patient walk 100 meters on level ground, taking forty-five or fifty steps a minute, with deep inspiration or expiration at each step. If the pulse runs up considerably with this and does not quiet down completely within a few minutes, he gives up the attempt at mechanical treatment for the time at least, and devotes his energies to relieve and rest the heart. But if there is no abnormal reaction, no dyspnea, he continues with the exercises, gradually increasing the distance and the slope, but always under constant medical supervision until certain that the exercise is borne without harm, and that the patient can be trusted to follow directions alone. Constant control of the urine is important—a progressive decline in the total output and increase in the specific gravity should warn to greater caution. In conclusion he emphasizes the necessity for exact knowledge as to the grade of the slope, not trusting to the eye, and he gives a road map of his region showing by different colors the roads with 0.5 per cent. grade, 5 to 10 per cent., 10 to 20 per cent. and over.

January, 1918, **28**, No. 1

37 *Action of Cold on Microorganisms. A. Q. Ruata.—p. 1.
38 Biology of Lice. A. Ilvento.—p. 10.

37. **Action of Cold on Micro-Organisms.**—It is generally accepted that cold inhibits the proliferation of germs but does not destroy them. Ruata's experiences, however, have demonstrated that a long enough exposure to cold will destroy the cultures beyond possibility of recuperation. The temperature was dry cold and kept constantly between — 3 C. and — 12 C. Thirty cultures of colon bacilli and other germs were placed in the refrigerator and some were withdrawn on successive days and incubated. By the fourth day only from three to forty-nine colonies developed, instead of the thousands of the second day, and no colonies at all developed after the fourth day. Similar results were obtained even with four strains of bacilli and one streptococcus isolated from putrid meat. The conflicting results that have been obtained by others were probably due to the fact that the contact with the cold was not long enough to have its action penetrate through the entire mass. Even one germ still living in the center of the mass would start a culture. But systematic permeation of the entire mass by cold of these degrees will certainly progressively sterilize it in time.

41 *Treatment of War Fractures. A. Serra.—p. 493.
42 Treatment of Grave War Wounds of Bones and Joints. F. Pancrazio, G. Querni and F. Miti.—p. 569.
43 *Partial Amputations of the Hand. F. Delitala.—p. 595.

40. **Vitalization of Artificial Limbs.**—Putti expatiates on the promising field opend up by Vanghetti with his idea of utilizing the muscles in the stump in such a way as to permit volitional control of the prosthesis. His latest article on this kineplasty was reviewed in The Journal, July 28, 1917, p. 321. Putti has been studying from this point of view 1,000 stumps and noticed that the functional value of a stump was by no means always proportional to the length of the stump. *The vitality of the muscles, however, is strictly dependent on* the state of the terminal segment of the stump. He was also impressed with the great power of recuperation of the muscles after long inactivity when the proper physical and surgical measures were applied. The power of volitional dissociated movements of different muscles persists long after amputation, and can be increased by training and exercise and especially by utilizing it for kinematization, that is, for vitalizing the artificial hand or foot. Thirteen cases are described with minute detail and seventy-nine illustrations, and the various types of artificial hands and legs constructed for kinematization are reproduced. He also describes the exercises devised to train the muscles to dissociated, effectual motor functioning. In one typical case the knee had been disarticulated and a month later the quadriceps had been tunneled, thus forming a flexor-extensor loop containing the patella. In twenty days the exercises were begun; by the thirtieth day a weight of 10 kg. could be suspended and moved for 3 cm. The tunnel is lined with a pedunculated flap of skin, sutured to make a tube. Plenty of sound skin is indispensable for lining the tunnel. The skin over the extensor region is usually stouter than elsewhere, and it and the muscles can be mobilized and stretched with strips of flannel, etc., stuck to the skin to which elastic traction can be applied.

It is quite a task to revivify the muscles of a stump and train the motor centers to a peripheral action and kinetic play which is fundamentally different from the normal, but experience has demonstrated that the resources of a muscle are infinite, both biologically and mechanically, and its motor centers are adaptable, while the innumerable resources of physiotherapy revivify and intensify the motor force of the stump. A number of tables are given of the findings in regard to the motor capacity of 200 amputation stumps compared to the length of the stump. They show that with the longer stumps the sacrifice of a few more centimeters of the bone does not modify the motor power. The man must be able to rotate the limb. No attempt is made at reunion of the stumps of the tendons. The men soon learn to do separately the movements for bending and stretching the muscles. One man rapidly learned to bend the motor loop sideways (radial), the impulse, he said, being the same as for abduction of the thumb.

41. **War Fracture of Long Bones.**—Serra gives an illustrated report of forty-one cases given treatment at the Rizzoli Institute at Bologna, and the various immobilizing devices used.

43. **Partial Amputation of the Hand.**—Delitala comments on the necessity for constructing the prothesis for each individual case, utilizing every scrap of possible motor functioning. He gives illustrations of numbers of such devices from those for a single finger to the whole hand, a total of fifty-two illustrations. The fifty crippled men included four with bilateral amputation. He emphasizes in particular the surprising leverage force left in the carpus, especially for vitalization of artificial fingers. It is possible to obtain with it functional results identical with those realized by Putti with the kineplastic loops described in abstract 40 above. Delitala and Putti both utilize a recording drum and kymograph to determine the amplitude and force of the movements, the rhythm of contraction, and the influence of exercise, training, etc.

44 *Amino-Acids in Urine from Debilitated Infants. S. Cannata.—p. 65.
45 *The Functioning of the Mammary Gland. A. Borrino.—p. 71.
46 *Palpable Intercostal Lymphatics in Infants. S. De Stefano.—p. 88.

44. **Amino-Acids in Infants' Urine.**—Cannata tested the urine of four cachectic infants for amino-acids. They were constantly present in large amounts, showing the disturbance in the intermediate metabolism in cachexia from syphilis, tuberculosis or other cause. The liver may or may not be damaged.

45. **Functioning of the Mammary Gland.**—Borrino insists that breast nursing can be resumed even after a long lapse. She has accomplished this in three cases after an interval of twenty-five, twenty-seven and forty-five days. She also insists that the child can be fed amply from one breast if the other is damaged beyond recuperation, or at least the child may require only a little supplementary feeding. Five case reports confirm her assertions. Gallstone trouble does not contraindicate breast feeding; she has had one patient nurse two children successfully although gallstone attacks returned at each of the two pregnancies. There had been no symptoms from the cholelithiasis in the interim. By letting the child suckle the breast every hour, but not for more than ten minutes, the glands resumed the secretion of milk, after twenty-five and twenty-seven days interim, in from three to six days up to eight days. The infants were about a month old at the time. In the third case the infant had never nursed well and there had been abscesses in the areolae. The child was trained anew to suck after forty-five days' suspension. It was given the breast of a wetnurse for two feedings after sucking the mother's breast for ten minutes. As the mother's milk increased in amount, the wetnurse feeding was changed for diluted cow's milk, but this was always given with the spoon, reserving the sucking efforts for the mother's breasts. The three children had been running down from severe digestive disturbances but all promptly recuperated when given their natural food.

46. **Palpable Lymphatics in Infants.**—De Stefano calls the discovery of enlarged peripheral glands in infants, Hochsinger's sign of tuberculosis. He tabulates the findings, with other clinical details, in fifty-six infants. In 55 per cent. of the total these palpable glands accompanied tuberculosis of the bronchial glands. In the other 45 per cent., palpable glands in the axilla were associated with diseases other than tuberculosis, inherited syphilis, rachitis or grave malnutrition.

51 *Traumatic-Emotional Dystrophy. G. Pighini.—p. 42.
52 *Tumors of the Temporal Lobe. P. Ciuffini.—p. 49. Commenced in No. 1, p. 1.

47. **Causalgia.**—Tenani argues that the prompt cure of causalgia by resecting sympathetic fibers testifies to the fact that the sympathetic nerve is incriminated in the pathogenesis. There may be some lesion or lesions in or involving the nerve trunk or the fibers encircling the trunk vessel or in the vessel itself. Resection of the sheath around the vessel generally removes the cause, and the causalgia disappears. He does not restrict his intervention to resection of the sheath of the artery but resects the sheath of the vein as well. This simplifies and facilitates the resection while it renders the benefit more certain and regular. The experience to date all speaks in favor of this method of treatment but the cases are still too few and too recent for a final judgment. They have already established beyond a doubt the

share of the sympathetic in the causation of the causalgia. The appearance of causalgic phenomena in certain cases where there is only partial interruption of a nerve, and the subsidence of the causalgic phenomena after removal of the cicatricial tissue and coaptation of the stump show that the sympathetic nerve is not the only factor involved. On the other hand, the absence of any improvement after the operation in certain cases of this kind renders the choice difficult between neurolysis and sympathectomy. Another fact that adds to the uncertainty is that many sympathetic fibers accompany the nerve trunks, independently of the blood vessels, and we are dubious whether to act on the nerve or on the sheath of the artery.

48. **Epidemic Dropsy.**—Leporini reports some cases in northern Africa of a low febrile state with vomiting and diarrhea, and then suddenly there develop anasarca, a peculiar eruption, and acute anemia and intestinal disturbances. It is the first time, he thinks, that this epidemic dropsy has been known in northern Africa. The necropsy findings in the liver and kidneys resemble those of amyloid degeneration. He is convinced of the infectious origin but accepts also a predisposition from some alimentary deficiency. This assumption suggests that epidemic dropsy might properly be called "infectious beriberi."

50. **Traumatic Pseudotabes.**—Mendicini describes a case of injury of the cauda equina from a scrap of shell in which the symptoms were those of pronounced tabes, extinction of the reflexes, ataxia when walking but not when seated or reclining, lancinating pains, and deranged sphincter functioning. The traumatism was in the lower lumbar vertebrae. It had induced, at first, total paraplegia. In connection with this case he reports one of pseudotabes caused by an extrameningeal traumatic polyradiculitis. In this the paraplegic phenomena were fleeting, and the functioning of the sphincters was intact. The cough and sneezing sign was pronounced in the first case but not in this one. In a third case described the diagnosis of lumbosacral hematomyelia seemed evident. The course of such cases clears up the diagnosis, as all agree that traumatic lesions of the cauda equina tend to improve, even in the cases which at first seem very grave. Improvement is especially likely when the symptoms take the form of pseudotabes, the expression of an incomplete lesion of the roots.

51. **Traumatic Emotional Dystrophy.**—Pighini's conclusions from study of the men with dystrophies of different kinds after minor war wounds have convinced him that when peace is once declared these affections will disappear. It is the war environment, the focusing of the attention on the wound which the man does not want to have healed, as this would mean his return to the firing line. All his thoughts and efforts are focused on perpetuating the wound and its results. If the nervous constitution is below par, to begin with, there may become installed a reflex dystrophy in time. In all such cases tested he found an intense reaction to atropin, with scarcely any reaction to pilocarpin, epinephrin or ingestion of glucose. There is ground for assuming that the thyroid secretion presides over the functioning and the tonification of both sections of the vegetative nervous system. The vagus, with its ramifications in the throat, stimulates the formation of the thyroid colloid on the one hand, while on the other the thyroid secretion stimulates and tonifies the vagus nervous system. Thyroid treatment supplies the stimulating hormon for both systems, but the sympathetic usually feels its action predominantly. When there is a tendency to autonomous miopragia and abnormal functioning on the part of the sympathetic, then thyroid treatment has a different action. It slows the heart impulse and the pulse, raises the blood pressure, and the oculocardiac reflex tends to become normal. In these cases of trophic changes in skin, muscle and bone, with traumatic psychoneuroses, he noted among the other somatic changes that the coagulation time of the blood was abnormally long. It is possible that further research may disclose a deficit in lime in the blood, or pathologic parathyroids. If these trophic changes were merely reflex phenomena, instead of requiring a predisposition and special psychic circumstances, they would be of common instead of exceptional occurrence. He regards as the most convincing of his arguments in favor of this view, that these dystrophies have never been encountered among prisoners of war in the Italian camps. The war wounds in them heal as in peace, as the men know their days of fighting are over. In the soldiers, dreading a return to active duty as soon as the wound is healed, the pulse is unstable, hypotension and tachycardia are frequent, as also dermographism, intensification of the muscle response to mechanical stimulation, and trophic manifestations, such as edema of the hand after a slight wound of one finger, patches of leukoderma, or symptoms suggestive of excessive or deficient thyroid functioning. In one man one leg developed myxedematous changes, which improved under thyroid treatment.

52. **Tumors in Temporal Lobe.**—Two operative cases are described in detail. They show that the temporal lobe can be divided into four zones, each of which has its own special symptoms. Jacksonian epilepsy originating on the paretic side of the body was noticed in one case. In one of the cases the spontaneous pressure pain was always localized mainly in the frontal lobe. The hearing was reduced early, as also the sense of smell. Word amnesia was pronounced in one case, also a tendency to sensory disturbances and aphasia. The changes in character were early and pronounced. One patient was a boy of 14 and great improvement followed the operation last June. The tumor is said to have been a spindle-cell sarcoma as large as a lemon. There had never been any signs of jacksonian spasms during the six months since the first symptoms had been observed.

53 *The Typhoid Mortality. P. Guizzetti.—p. 82.
54 Banti's Disease as a Morbid Entity. A. Ferrannini.—p. 89.

53. **Typhoid Mortality.**—Guizzetti analyzes the typhoid data from 1860 to date at the Institute for Pathologic Anatomy at Parma. He made the necropsy himself in 160 of the total 378 cases. In only three cases were the intestines found intact. In one child of 6, an ascaris seemed to be responsible for the fatal perforation. The cases with perforation seemed to be more numerous in certain epidemics than in others. Lesions in the lungs were manifest in over 34 per cent., mostly hypostatic pneumonia, but pleuritis was observed in only five cases. In each the typhoid bacilli were responsible for the infarcts in the pleura. Two of the cadavers showed a general hemorrhagic diathesis but in the entire 378 cases no indications were found of typhoid lesions in bones or the male genital organs, and none have been observed among the 892 soldiers with typhoid in his field hospital service. Diphtheria, erysipelas and bacillary dysentery sometimes complicated the typhoid, but in all his experience he has never met with a complicating eruptive disease, measles, scarlet fever or variola.

55 *Vagotony with Gastric Ulcer. O. Ayres.—p. 433. Commenced in No. 50, p. 425.

55. **Delirium of the Vegetative Nervous System.**—Ayres says that nothing less than the term "delirium" will fit the case described. The young woman never at any time presented any of the usual manifestations or stigmata of hysteria. The family was healthy, but the young woman suffered from dysmenorrhea and for the last two years had presented symptoms suggesting gastric ulcer. Then came sudden choleriform diarrhea and later intense pains from the gastric ulcer but localized in the abdomen. The pains were so intense that they threatened heart failure and the patient had to be kept under the influence of opium or chloral during the twenty-four hours they lasted. Then came convulsive spasms of the stomach, esophagus, throat and diaphragm. These spasms persisted even under the influence of 4 gm. of chloral and during syncopes. Application of galvanic electricity [illegible] the spasm, and no treatment seemed to have

influence. The convulsions were not merely choreiform movements—the pulse disappeared completely, and the entire thorax was brutally shaken, leaving the young woman bathed in sweat and fainting. Even under 4 gm. of chloral the convulsions returned every five or ten minutes at longest. They kept up for nearly two days; a fatal termination seemed inevitable, but the patient's strength was maintained with nutrient enemas and saline as the local convulsions alternated repeatedly with lipothymias. All this sequence of symptoms occurred during a menstrual period. As this came to a close the convulsions grew less frequent, and finally all this vagotonic and sympatheticotonic *delirium* subsided. The last drug given before the sudden turn for the better was 3 gm. of potassium bromid by the rectum. Ayres regards the whole syndrome as a "tempest in the vegetative nervous system brought on by the gastric ulcer."

63 Puberty. Blanc y Fortacin.—p. 45.
64 Diverticulum in the Bladder. P. Cifuentes.—p. 58.

59. **Scleroderma with Nodules.**—The young woman was of a healthy family and seemed healthy herself except for the scleroderma and lumps in all her fingers except the thumbs. These disturbances had developed in the last four years. No possible cause could be discovered but improvement followed tentative suprarenal treatment. In two of the fingers the nails have grown—for the first time since the nodules developed. These two fingers alone had been anesthetized for resection of a nodule, and epinephrin had been used with the local anesthetic. This suggests that local application of epinephrin should supplement the general suprarenal treatment.

60. **False Membranes in the Peritoneum.** — Escribano describes a few cases from his own experience in which false membranes had formed on a segment of the bowel. In one man of 28 this mesenteriform membrane had developed on the upper segment of the jejunum and ileum. It was entirely free of the greater omentum, colon, and abdominal walls but was continuous with the mesentery by the intermediation of the serous sheath of the intestine. He cut away the entire false membrane which had been immobilizing the intestine, working between two ligatures, and covering raw surfaces with peritoneum. Complete subsidence of all the previous disturbances gradually followed. The membrane had covered three meters of the bowel. The resulting kinking and other obstructions amply explain the tendency to gastric or duodenal ulcer in such cases, and confirm the possibility of a permanent cure when the bowel is released from the grasp of the false membrane. This "medical surgery" seems to be all that is necessary. The features of these false membranes suggest a congenital rather than an inflammatory origin. In two of the groups described there were comparatively recent membraniform adhesions, evidently result of old and cured pericholecystitis. Years of suffering were cured at one *stroke* by breaking up the adhesions. In another case there was no trace of a mesentery for the transverse and descending colon while the gastrocolic omentum was so large that part sagged an inch or two below the iliac crests, and the stomach sagged low down.

62. **Vitamins and Hygiene.**—Pittaluga's presentation of the present status of our knowledge in regard to vitamins is based largely on editorials and abstracts in The Journal. He concludes with the statement that it might be well to appoint an official like the ancient Roman praefectus annonae to equalize the markets at different points and ensure the proper distribution of foodstuffs on the basis of their vitamin content. Hygiene, he adds, is the art of applying scientific data to the conservation and perfecting of human life. When art has man for its object, individually or collectively, it is rightfully called political economy. The enlightened must work to save the people in spite of themselves.

Prensa Medica Argentina, Buenos Aires

Jan. 10, 1918, **4**, No. 22

65 *Syphilitic Meningitis. M. R. Castex and R. Pradere.—p. 291.
66 *Dwarf Tapeworm in Argentina. S. E. Parodi.—p. 294.
67 Normal Beef Serum in Treatment of Anthrax. III. J. Penna, J. B. Cuenca and R. Kraus.—p. 297. Continuation.

65. **Syphilitic Meningitis.**—A man of 64 was brought to the hospital unconscious, and the clinical diagnosis was syphilitic meningitis plus a gummatous affection of the right lung. This presumptive diagnosis was confirmed by the recovery under specific treatment. Syphilitic meningitis may develop in an acute form with stormy onset, or it may resemble tuberculous meningitis in its gradual development. The main difference between acute meningitis of syphilitic origin and others is the promptness and the intensity of the psychic disturbances. The cases of tuberculous meningitis in children and adults which have been published as cured by mercury and iodid treatment probably in reality had been syphilitic meningitis, with the syphilis unrecognized. Two cases are described in which the symptoms came on gradually. Headaches and forgetfulness so that the man was unable to find his way home from his work lasted for two or three weeks, and then vomiting followed, with stupor. The Wassermann test was negative but the entire absence of fever and the high pressure in the spinal fluid, the intense Kernig sign and cerebellar ataxia confirmed the diagnosis of syphilitic meningitis and complete recovery followed in less than ten days of mercurial treatment. In the other case the meningitis came on with high fever, delirium, and symptoms of nephritis. Under mercury and iodid both the meningitis and the nephritis subsided completely. Although there was no history of abortions, the ten children all presented stigmata of syphilis.

66. **Tapeworm in Argentina.**—Parodi found ova of the *Hymenolepis nana* in 8 per cent. of the children's stools examined at Buenos Aires and in 0.66 per cent. of adults' stools. He describes here twelve cases of this helminthiasis in children. As these dwarf tapeworms infest the lower intestine they cause comparatively little disturbance. In a few of the children there were gastro-intestinal symptoms and two presented nervous phenomena resembling epilepsy. One girl of 14 had these epileptiform attacks every week or two for four years. Twitching of the head or left arm was the first symptom, and then came loss of consciousness for a few minutes. Once the convulsion lasted for half an hour, the tongue was bitten and the child was unconscious for several hours. Tonics and sedatives had been ordered by various clinicians, but one noticed finally that the child's nose seemed to itch a great deal, and examination of the stools then revealed the ova and under thorough and repeated male fern or thymol treatment hundreds of helminths were passed and there have been no nervous symptoms since. In another case a boy of 13 apparently healthy otherwise, had fallen unconscious for three or four minutes, the eyeballs rolling up. These attacks were repeated four or five times a day and there were frequent headaches. After six months of this the stools were examined and the dwarf tapeworm ova and endameba cysts were found in large numbers.

68 *Aphorisms of a Urologist. S. V. de Castro.—p. 65.

68. **Aphorisms of a Urologist.**—Among de Castro's aphorisms, which fill five pages, is one reiterating the importance of the ear-bladder reflex, especially with a tendency to prostate obstruction: The sound of water being poured from one vessel into another increases and may even start expulsive

contraction of the muscular fibers in the bladder. He says that deep forcible inspirations aid the *prostaticos* to void urine, as this aspirates the blood into the chest, which relieves engorged veins below and tends to reduce congestion in the prostate region. The action of the balsamics given for gonorrhea is chiefly displayed as they are eliminated through the diseased mucosa. It is important therefore to keep the diseased mucosa clean so that elimination can proceed unimpeded. This is particularly necessary with gonorrheal vaginitis. He declares that intra-urethral injections wash the germs into previously uninfected regions, so that they have done more harm to the human species than the gonococcus itself. Copaiba and the other balsamics induce diuresis by their action on the kidney, and they are liable to bring on lumbar pain, vesical tenesmus and albuminuria, which must not be misinterpreted. Persons with sluggish metabolism and elimination seem to be particularly predisposed to the chronic form of gonorrhea. Well treated gonorrhea never leaves urethral stenosis. The asepsis of the catheter may be complete but it takes up germs as soon as it touches the meatus. His final aphorism is to the effect that singing with all one's lungs promotes diuresis.

69 *Intra-ocular Sarcoma. J. De Salterain.—p. 1.
70 *Congenital Segmentary Edema. J. A. Bauza.—p. 6.
71 *Dissecting Perimastitis. F. Cortabarria.—p. 9.
72 Infantile Scorbutus. R. M. del Campo.—p. 15.
73 *Typhoid Superposed on Paroxysmal Hemoglobinuria. A. Ugon.—p. 20.

69. **Intra-Ocular Sarcoma in Children.**—De Salterain cites among others a report on thirty cases of sarcoma of the choroid compiled by Argañaraz of Buenos Aires in 1915, but none were in children. He has been unable to find records of more than thirteen or fourteen cases in children, but he has himself encountered two cases in infants. In both cases prompt enucleation was done, and the children have shown no sign of recurrence during the intervals of four and eight years since. One was a girl of 6 months, the other a boy of 22 months. The children seemed to be healthy otherwise. In the first case there was no inflammatory reaction, but the child cried and became restless when the sound eye was covered, confirming that vision was lost in the other.

70. **Segmentary Edema.**—Bauza noticed the day after the birth of a girl infant that both of the infant's feet showed extreme edema, but there was no trace of edema elsewhere. Under massage and application of heat it gradually subsided somewhat but was still pronounced, and harder, by the fifth month. Milroy has reported a family in which there were twenty-two cases in the course of six generations, but in Bauza's case no familial or hereditary factor was manifest.

71. **Dissecting Perimastitis.**—Cortabarria's two patients were parturients, apparently entirely healthy except for lymphangitis of the mamma. The breast was treated with tincture of iodin. Ulceration followed and a Bier vacuum glass was applied in each case with application of ice in one case and further iodin treatment in the other. The aspiration into the vacuum glass had evidently been too severe, and this traumatism in connection with the extravasation of serous fluid induced by it had favored the spread of the existing lymphangitis. It invaded the region around the mamma, causing chills, high fever and dissecting perimastitis. One woman was left with diffuse infiltration of the mamma after recovery. The other developed phlebitis in the left leg and an embolus in the left lung, with symptoms suggesting thrombosis in the external iliac vein. Streptococci were cultivated from the blood just before death. He regards the intensive application of the vacuum glass as the principal factor in these complications.

73. **Typhoid with Hemoglobinuria.**—The boy of 7 had been subject to essential paroxysmal hemoglobinuria for four months when he developed typhoid. There were no signs of inherited syphilis, but the tuberculin reaction was positive. Fever, depression and bronchopulmonary symptoms were the only signs of typhoid until agglutination became positive by the end of the fourth week. The case further teaches, it is emphasized, the necessity for vaccination against typhoid for the personnel of hospitals and for all the inmates when there are cases of typhoid in the building. This child evidently contracted the typhoid from a typhoid case in the hospital.

74. **Hookworm in Argentina.**—Mayor and Borzone report the first case of autochthonous ankylostomiasis in a man who had been living constantly in Argentina for many years. The *Necator americanus* was found numerous in the stools.

76. **Syphilis in Argentina.**—Raices comments on the alarming spread of syphilis in Argentina. The number applying for treatment of syphilis at the clinic for skin diseases and syphilis has almost doubled in the last five years. All ages, both sexes and all classes of society show this constant increase, while the public authorities, he reiterates, are doing nothing to check its spread which grows more and more difficult every day that passes. During the last four years the source of the infection has been investigated in every case of syphilis in the clinic, and in 95 per cent. it was traced to the licensed brothels under municipal supervision with weekly medical inspections.

88 Indicanuria with Deficient Diet. A. Phocas.—p. 33.

85. **Crawling on Hands and Feet to Relieve Heart Disease.**—Cecikas reports eight cases in which persons with distressing paroxysmal tachycardia or other heart symptoms obtained great relief by getting down on all fours. One man of 32, emaciated from bacillary dysentery, found this the only means of relieving paroxysmal tachycardia. After the dysentery had been cured by serotherapy, there were no further paroxysms. Other patients were corpulent and suffered from a tendency to angina pectoris or to edema of the lung. Getting down on all fours, and standing still or crawling to and fro like an animal in a cage, brought relief each time. One of the patients was very thin and nervous, with attacks of palpitation and distress, insomnia, etc. By getting up in bed and crawling around on all fours she obtained relief and slept afterward. A change to the country and hydrotherapy cured her. The change to the quadruped position changes the statics and the distribution of fluids in the body, and thus cannot fail to modify the heart action. The pressure in the chest is reduced which facilitates the reflex of blood, while the viscera change their relations to each other to some degree, and the heart changes its position notably, both perpendicularly, horizontally and twisting on its axis, and its relation to the abdominal viscera is altered. The influence of indigestion and tympanism on the functioning of the diseased heart is well known. He has seen arrhythmia subside completely in children kept fasting for a day, and he has witnessed prompt recuperation of the heart in typhoid that seemed on the point of complete heart failure, when a tube

was introduced high up in the bowel to permit evacuation of gases. He adds that it is possible that toxins generated in the bowel may slide down, in the all fours position, to some point where they may get modified or neutralized. This position may also modify the glands with an internal secretion. In conclusion he cites Hirtz' statement that a change to the quadruped position brings such relief in pericarditis with much effusion that this relief may be regarded as a pathognomonic sign of this disease.

86. **Oxaluria and the Diazo Reaction.**—Phocas relates that in twenty-one clinical patients there was oxaluria plus urobilinogenuria in all but three.

91 Actions of Cholin, especially on the Circulation. Y. Ozaki.—p. 143.
92 *Pathogenesis of Communicating Hydrocele. H. Tsuji.—p. 207.

89. **Action of Bacteria on Tyrosin.**—Tsudji subjected tyrosin to the action of proteus bacilli, and other specimens to the ction of the subtilis. The products with the proteus were vays of the dextro type; with the subtilis they were always the levo type. He says that he knows of nothing analogous to this in pure chemistry or in biologic chemistry. The d-oxyacid product was always obtained with the proteus, the l-oxyacid, with the subtilis, regardless of the optic components of the tyrosin. He experimented both with d-tyrosin, l-tyrosin and dl-tyrosin.

90. **Implanting Nerve in Paralyzed Muscle.**—Doi's experiments on young rabbits gave encouraging results. He exposed the nerves at the back of the knee through a 3 cm. incision, resected as long a stretch of the tibial nerve as possible, and severed the external popliteal nerve in the peripheral portion. Then he implanted the central stump of this popliteal nerve in the neurectomized gastrocnemius muscle, and fastened it to the muscle with a few stitches. Seven such experiments and the ultimate microscopic findings are described in detail, as also five experiments in which the nerve was thus implanted in a long paralyzed muscle. In other experiments he studied the changes undergone by the neurectomized muscle. The results obtained encourage the hope that a long paralyzed muscle can be restored to functioning by implanting another motor nerve, provided the muscle is only in simple atrophy and does not show too extreme a degree of degeneration. No evidences of hyperneurotization were observed up to eighty-five days when another motor nerve was implanted in sound muscle. In the further growth of the regenerating nerve fibers, the presence of the old degenerated nerve tract seems to play a great rôle, as is illustrated in a colored plate.

92. **Communicating Hydrocele.**—Tsuji applies this term to hydrocele communicating with the peritoneal cavity, and describes thirteen cases in which he corrected conditions by a laparotomy. The fluid was derived mainly from the peritoneal cavity and signs of simple chronic peritonitis were found in nearly every case although it had been quite latent in several. The peritonitis had evidently been brought on by constipation, chronic indigestion and ascaridiasis. The patients were mostly boys from 5 to 18, but there were three men of 22, 37 and 42. In two of the cases the hydrocele had subsided for five months or seven years but then returned, but the cure was complete in every case when the internal opening of the vaginal process was permanently closed with a purse-string suture. No signs of tuberculous peritonitis were found in any case and only two of the patients gave a faint Pirquet tuberculin reaction.

93. **Acute Edema of Anterior Lip of Uterine Cervix.**—The edematous swelling protruded from the labia in the case described, but gradually subsided and delivery followed three days later. Knoop and van Dongen review the literature on the subject and discuss the probable factors involved. In 1912 Meyer compiled twenty-two cases of the kind.

94. **Anatomy of the Pituitary Body.**—Woerdeman analyzes the lobus bifurcatus of the pituitary body and its origin as studied on various vertebrates. It is very small in man, as he shows in his illustrations, but it is very important on account of its proximity to the chiasm and the floor of the third ventricle. Its location in the subarachnoidal space suggests that it has some special function. It cannot be removed with the rest of the gland without resecting the diaphragm of the sella turcica, and even then cannot be removed without danger of injury of nerve tissue as it extends toward the base of the brain. Another significant feature of this bifurcated lobe is that it may explain the cysts that develop back of the stem of the pituitary body.

95. **Intratracheal Treatment of Asthma.**—De Levie incriminates spasm of the bronchial muscles as the cause of asthma, and ascribes this to overexcitability of the innervation. The logical treatment is to reduce this overexcitability, especially as it has been found that anesthetizing the region for bronchoscopy seems to arrest and cure attacks of asthma. Ephraim, Pieniazek and Novotny have each reported the cure of asthma by systematic application of novocain plus epinephrin. No untoward by-effects were ever observed. De Levie has applied this method of treatment in fifteen cases and seven may be regarded as cured, no attacks having returned during about a year to date. Six were much improved but still have an occasional attack and return for further treatment. The attacks are rare, however, and much milder. No benefit was observed in one young woman with hysteric paralysis of the vocal cords, and in another case in which the asthma was of twelve years' standing and the expectoration from chronic bronchitis so profuse that probably the medication was mostly expelled without getting absorbed. The technic is simple; a flexible tube carries the spray directly into each bronchus in turn, thereby acting on the nerve terminals and thus arresting the cause of the spasm of the bronchial muscles. In his later series he used an atomizer with a tube bent twice at a right angle. The distal, downward bent portion is 10 cm. long. After cocainizing the larynx, the tube is introduced under the guidance of the mirror. It reaches down below the cleft of the vocal cords. Then the fluid can be sprayed in gently, taking as much time for it as you wish. In order to get as much spray into the air passages as possible, the atomizer bulb is squeezed synchronous with each inspiration. He used various sprays; besides the novocain-epinephrin mixture, he tried tannin, menthol or Ems salts. The application was made twice a week at first and then once a week or with longer intervals. In some cases the course lasted for two or three months. All were old inveterate cases, mostly with chronic bronchitis, in some with emphysema, so that 50 per cent. cured and all improved but two, seems a satisfactory result.

A BLOOD SUGAR TOLERANCE TEST[*]

N. W. JANNEY, M.D., PH.D.
AND
V. I. ISAACSON, B.S.
NEW YORK

There is need both of a better general understanding of sugar tolerance and of a reliable sugar tolerance test. The customary clinical method has been to give the patient by mouth 100 gm. of glucose dissolved in more or less water and to determine the presence and amount of a possibly resulting glycosuria. This rough procedure is very uncertain. It has been justly criticized by Allen,[1] and also by Hulton and Taylor[2] on the basis of experimental evidence. These investigators called attention to the fact that there is no actual upper limit to sugar tolerance so far as normal individuals are concerned, as they are able to tolerate as much glucose as they can retain. Therefore it is argued that increased tolerance must be nonexistent. This objection has cast doubt on the whole conception of increased sugar tolerance. On the contrary, a *decreased* power of assimilation of glucose does certainly occur as, for example, in diabetes. There is, of course, no question as to the value of sugar tolerance in these conditions. A second objection to the usual clinical test may be raised, namely, that oral administration of glucose is uncertain, as variations in the alimental absorption cause discrepancies in the results. This is an obvious possibility, as rate and concentration at which the sugar enters the circulation are controlling factors. Still other objections may be raised. One hundred gm. of glucose have been arbitrarily administered to persons weighing 100 or 200 pounds. The amount of water given with the glucose has never been properly standardized. These factors very probably influence the results of the tolerance tests.

Again, it must be remembered that faulty inference as to the sugar tolerance is liable to be made when the urine alone is tested, for glycosuria may occur without elevation of the blood sugar. Moreover, no glycosuria may ensue on marked elevation of the blood sugar. Thus both incipient diabetes mellitus and renal diabetes are characterized by glycosuria in the tolerance test. In renal diabetes there is, however, an inconsequential rise in the blood sugar, while in true diabetes the opposite is the case. Hyperglycemia without glycosuria, such as occurs in chronic interstitial nephritis cases tested for their blood sugar tolerance, may lead to the wrong conclusion, that the tolerance is increased when the actual condition is sugar retention.

The subcutaneous and intravenous methods have been used in an attempt to avoid these disturbing influences — the former, however, with no success.

Wilder and Sansum[3] and Sansum and Woodyatt[4] have, however, worked out what is undoubtedly the most accurate method as yet devised for testing the urinary glucose tolerance. By using intravenous injections and carefully controlling the rate of glucose supply to the blood with special apparatus, they obtained results that checked well, and concluded that the intravenous injection of 0.8 gm. of glucose per kilogram of body weight per hour represented the upper limit of tolerance of normal persons. When more sugar is injected, glucose appears in the urine. Sansum and Woodyatt, in a careful critique, very properly call attention to the inaccuracies of the usual clinical methods of tolerance testing. But serious practical objections may be made against their own method. Expensive apparatus and a venous puncture are required. This will always stand in the way of its general adoption for clinical purposes.

It remained desirable, therefore, to devise a tolerance test that would be more convenient and sufficiently accurate. We have consequently returned to the study of oral administration of sugar. The possibility of delayed or defective absorption from the alimentary canal had first to be controlled. This factor has been supposed by various authors greatly to influence the results of tolerance tests. Several years ago, during a previous investigation of sugar formation from protein in diabetes, it became necessary to make some experiments concerning this point. Much less variation was found in the absorption rate, even of solids, than had been supposed to exist. When various mechanical factors were controlled, absorption took place at such a regular pace that curves representing the nitrogen and, indeed, the sugar excretion following protein ingestion showed a remarkable similarity in several experiments. Reference may be made to the original articles[5] for details. Mendel and his collaborators[6] have come to the same conclusion in elaborate studies which cannot be discussed here. Water soluble substances are absorbed at a still more uniform rate. From the results of these physiologic experiments, it appeared very likely that pure glucose solutions of constant concentration given per kilogram of body weight would be absorbed even by different persons at a fairly uniform rate. It is obviously necessary to study the rate of alimentary absorption of sugar. Blood sugar estimations enable us to do this. It is known that the blood sugar is elevated when carbohydrates are ingested. When the factors mentioned below were observed, it was found that following glucose ingestion normal individuals uniformly reacted with a definite degree of hyperglycemia. Thus, by observing the blood sugar at short intervals, it was possible to map out a normal blood sugar curve. This has been found to be so constant, both by ourselves and by others,[7] that a very long series of controls was not indicated.

The necessary factors requiring observance are:

1. To avoid the influence of food, the subject must be fasting at the time of the test. This hunger period is fifteen hours in our technic.

2. The blood sugar level must be known before the glucose is fed, since hyperglycemic and hypoglycemic states markedly affect the blood sugar tolerance. (See experiments in this article.)

3. The blood sugar assimilation curve must express the velocity of the hyperglycemic response to sugar feeding. This is obtained by the ingestion of a definite weight of sugar per kilogram of body weight of the subject. The sugar solution must have a definite concentration. The necessary time factor is supplied by estimating the degree of the resulting hyperglycemia at fixed intervals.

4. The glucose used must be pure, as we have found in former experiments that glycosuria may be caused or increased as a result of toxic substances ingested with the sugar.

5. Exercise should be limited during the time of the test, as it has been demonstrated both clinically and experimentally that bodily movement usually increases glucose combustion. This was accomplished in our series of experiments by confining dogs to cages and obliging patients to sit quietly during the test periods.

6. The rate of alimental absorption must be controlled. This has already been discussed. With observance of these factors, the *blood sugar tolerance* test as performed by us is as follows:

TECHNIC OF THE BLOOD SUGAR TOLERANCE TEST

The patient fasts from 7 p. m. one day until the test is completed the following morning. Meantime the patient's weight is ascertained and the glucose drink prepared by dissolving in water a weighed amount of glucose equivalent to 1.75 gm. of the sugar for every kilogram (2⅕ pounds) of this weight. For each gram of glucose, 2.5 c.c. of water are used, that is, 10 c.c. of water for 4 gm. of glucose. The juice of one lemon may be added for flavoring. At an early morning hour the blood sugar is determined. As soon as conveniently thereafter, the patient drinks the previously prepared cooled glucose solution. The mouth may, if desired, be washed out with a swallow of water reserved from the measured quantity for this purpose. Exactly one hour after the sugar drink has been taken, the blood is withdrawn for a second sugar determination, and a third time one hour later, that is, two hours after the sugar drink has been taken. If the tolerance is normal, the difference between this third estimation and the fasting value seldom exceeds 0.01 per cent. (Table 1).

The determination made at the end of the first hour is not strictly necessary, but is helpful in determining the height of the sugar curve. If the tolerance is decreased, the determination made at the end of two hours will detect persistent hyperglycemia, the extent of which may, if desired, be ascertained by further hourly determinations. The presence of hypoglycemia or hyperglycemia is, of course, indicated by the determination of the fasting sugar level, which consequently enhances the value of the test. Up to the present it has been our custom to collect a twenty-four hour specimen of urine, beginning at the time of ingestion of glucose and determining the presence and amount of glycosuria. This yields additional information, and is corroborative when the subject's tolerance is diminished. It should be noted that not one of the entire list of normal persons whose curves appear in the protocols showed any glycosuria on the standard amount of sugar fed. The blood test is much more delicate and gives more information than the urinary.

TABLE 1.—BLOOD SUGAR TOLERANCE TESTS ON NORMAL INDIVIDUALS*

Control	Before Glucose *Ingestion*	After Glucose Ingestion				Urinary *Glucose*

* We are indebted to Dr. Fergus Butler of the Metabolism Clinic, New York Post-Graduate Medical School and Hospital, for several blood sugar tests.

† High blood sugar but a normal curve.

The blood sugar tolerance test requires at least two or more blood samples taken at short intervals. We have found it inadvisable, therefore, to use any method requiring venous puncture, which demands considerable technical skill for frequent observations in the same patient, and have accordingly adopted Epstein's micromodification of the Lewis-Benedict method, as shown above. The technic is simple and has the advantage of requiring only a few drops of blood, taken, as in a blood count, from the finger tip. In an extensive experience we have been unable to obtain the extreme accuracy claimed for this technic. However, the results are still quite satisfactory clinically, as the error in our hands has not exceeded 7 per cent. and, indeed, rarely 4 per cent. Duplicate determinations were made in every case in the work reported in this article. They agree excellently. Even a 7 per cent. error does not detract from the clinical value of a blood sugar estimation; for whether a given result is, for example, 0.090 or 0.096 per cent., has no very serious significance. The technic is easily acquired even by one unaccustomed to delicate chemical procedures. We have found it advisable to prepare pure 0.10 and 0.20 per cent. glucose solutions at intervals, and to run blank determinations on these in order to detect imperfections in the reagents used, as well as to determine whether the standard color tubes are correct.

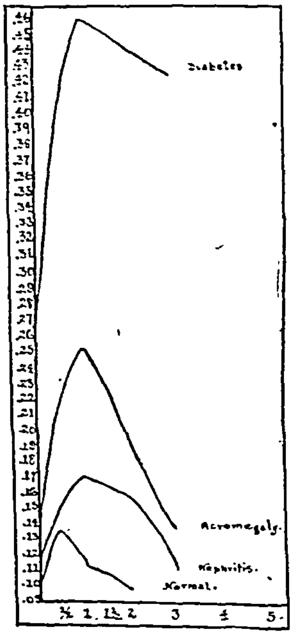
The hyperglycemic response to the tolerance test gives from 0.12 to 0.14 per cent. glucose in most normal cases, the normal fasting level of 0.10 per cent. being reattained in an hour and a half, or two hours at most. This has been observed in isolated cases by others.[8] In morbid conditions three, four or even five hours may be required.[9]

INDICATIONS

Obviously, all the usual indications for blood sugar estimations are here included. Such are diabetes, nephritis and disturbances of the various ductless glands. It is the belief of many that a sugar tolerance test is frequently indicated in diabetes. In most cases, however, we have found this test, and indeed the use of any tolerance test necessitating the use of glucose, to be usually of more scientific interest in diabetes than of practical value. The blood sugar curve is greatly prolonged in this disease, but this information is superfluous on account of the presence of other symptoms. Vastly more important is it, however, to ascertain how the diabetic reacts to a diet containing varying proportions of carbohydrate, fat and protein than it is to determine his tolerance to sugar, a substance he usually cannot be permitted to include in his food. When, however, it comes to the very mild cases which only occasionally show glycosuria on a full diet, the tolerance test is most useful, for one of the first symptoms is a prolongation of the blood sugar curve with hyperglycemia. It is probable that the test will become of value in differentiating renal diabetes from diabetes mellitus. A case of renal diabetes showed a normal blood sugar value and a typical tolerance curve, the highest point reached being 0.12 per cent., yet very definite glycosuria was present. Thus increased renal permeability without hyperglycemia may coexist.



Blood sugar tolerance in diabetes, acromegaly and nephritis, as compared with the normal. The horizontal line represents the hours, the vertical line indicates the percentage of blood sugar. Curves in cretinism and exophthalmic goiter are in course of publication.

Aside from the tolerance test, a study of the blood sugar in diabetes is yielding results of increasing interest and value. In glycosuric individuals the degree of hyperglycemia is to a certain extent a measure of the severity of the case in question. In sugar-free cases a high blood sugar approaching 0.17 per cent., the level at which glycosuria usually begins, indicates the necessity of fasting or further reduction in the diet. On the other hand, a fall of the blood sugar to the normal level in a diabetic formerly showing hyperglycemia indicates that the tolerance has increased. A trial addition of carbohydrate food may now be made. There is, however, a group of diabetic cases which show hyperglycemia above 0.17 per cent. even when the urine is sugar-free and renal involvement can be excluded.[10]

In chronic interstitial nephritis there is a tendency for the blood sugar to remain at the upper level of the normal, or higher. This is usually a retention phenomenon. In general, blood sugar values higher than the normal, accompanied by a prolonged or delayed blood sugar curve with the absence of glycosuria, are indicative of nephritis.[11]

The relation of the blood sugar to the endocrine conditions has been studied by us for some time past. It was first found that thyroidectomy is followed by hypoglycemia,[12] which is therefore to be ascribed to a hypofunctional condition of the endocrine glands. Hypoglycemia has been detected in cretinism, myxedema, Addison's disease[13] and hypophysial dystrophy.[14] We have found it constantly present in muscular dystrophy.[15] But few studies have been made of the blood sugar tolerance in these conditions. We have detected a delayed blood sugar curve in cretinism, myxedema, acromegaly and muscular dystrophy. It has also been recorded by others for acromegaly.[10] It is to be expected, therefore, where other hypoglandular conditions exist. This is a very interesting observation, for it would naturally be expected that the lower the blood sugar level the more quickly the ingested sugar would be removed from the blood. This tendency to a delayed tolerance curve may be taken as an indication that carbohydrate metabolism is disturbed in hypofunctional activity of the endocrine organs. A hyperglycemic response and a delayed blood sugar curve have been observed by us in all cases of hyperthyroidism and exophthalmic goiter tested. This evidence of imperfect carbohydrate assimilation suggests that dysfunction rather than hyperfunction of the thyroid is the underlying condition in exophthalmic goiter. The delayed curve is much more valuable than hyperglycemia in this condition, for certain cases of hyperthyroidism exhibit the former in the tolerance test, yet the fasting blood sugar is normal or subnormal.

[9] The directions given above have been followed in obtaining the results recorded in this article. The technic recently described by Hamman and Hirschmann (see end of article) has the advantage of using less glucose than in our experiments but can be criticized as the water and glucose are not standardized to the unit weight of the individual. The following modification is therefore suggested for future work: to use 1.5 gm. glucose per kilogram of patient's body weight. For each gram of glucose to use 3 c.c. of water. The other directions to remain as described in the text.

The test here suggested unfortunately is of no aid in the differential diagnosis of endocrine diseases in the absence of specific clinical symptoms, for the disturbances of carbohydrate metabolism detected by it are caused by various dysfunctionating ductless glands.

In the first part of the article it was mentioned, in regard to an upper limit of glucose tolerance, that such a condition has been doubted to exist, since normal persons could take increasing amounts of glucose without the appearance of glycosuria. A few grams of sugar, however, usually do appear in the urine of such individuals when very large quantities of glucose are ingested. Increased sugar tolerance with absence of glycosuria has been frequently reported in hypofunctional endocrine disturbances, such as hypophysial dystrophy, in which condition even 500 gm. of glucose have failed to cause glycosuria. The blood sugar tolerance test affords interesting insight into the nature of the increased tolerance thus observed, for it is here that we detected hypoglycemia, which in all probability is the cause of the increased tolerance thus observed. Sugar tolerance tests[17] performed by us on thyroidectomized dogs never showed as great a rise in the blood sugar following ingestion of glucose as did normal animals similarly examined. It is evident from this that more glucose can be assimilated in the case of the athyroid animals without causing glycosuria, and that this is probably due to the fasting low blood sugar level in these animals. As already mentioned, there is a tendency to a delayed sugar curve in these conditions; but this tendency is never sufficient to produce hyperglycemia and glycosuria, the hypoglycemia being the controlling factor

CONTRAINDICATIONS TO THE BLOOD SUGAR TOLERANCE TEST

Contraindications are irritable stomach in neurotic conditions and grave gastro-enteric diseases when delayed absorption might interfere with the results. Gastrectasia, atrophy of the mucosa, extensive ulcerations, or adhesions preventing normal peristalsis can conceivably affect the absorption rate and invalidate the test.

ADDITIONAL NOTE

The blood sugar tolerance test has been in use at the Montefiore Home and Hospital for the past two years. It was first discussed in a paper[12] read before the Society for Experimental Biology and Medicine, Feb. 21, 1917. Dr. Hamman has kindly called our attention to a preliminary report[18] of his work with Hirschmann on the same subject, read May 10, 1916, before the Association of American Physicians, appearing in March, 1917. We regret that these important data came to our notice after this paper had been written and cannot be conveniently incorporated in the text. Our detailed technic was described in this paper[19] read before the Society for Experimental Biology and Medicine, Nov. 21, 1917.

Nov. 17, 1917, a splendid article by Hamman and Hirschmann[20] appeared, reporting practically the same results as obtained by us.

THE TRANSPLANTATION OF BONE

W. E. GALLIE, M.D.

AND

D. E. ROBERTSON, M.D.

TORONTO

During recent years the science of bone transplantation has been occupying the attention of orthopedic surgeons to a steadily increasing degree. While the earlier operations were pure experiments attended by success or failure, depending on whether the surgeon chanced to employ the principles that are essential to success, the mass of evidence now at hand as the result of experimentation on animals has clearly outlined these principles and placed the clinical employment of the procedure on a sound scientific basis.

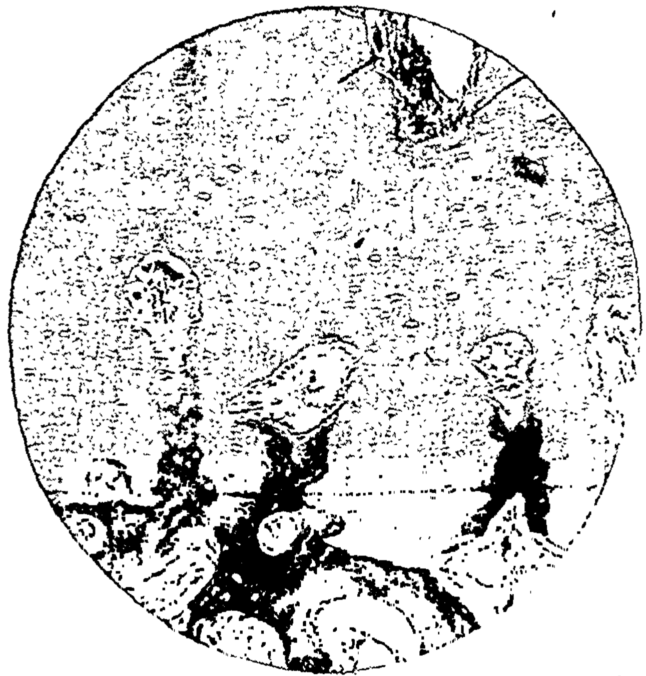

Fig. 1.—Low power photomicrograph taken at the medullary edge of an autogenous bone graft, three weeks after operation. It shows the union of the graft to the cancellous medullary bone; the invasion of the graft by the proliferating osteoblasts, large cavities being formed in its substance; the laying down of new bone on the walls of these cavities; the disappearance of the cells from the lacunae, and the reestablishment of the circulation as seen in the large haversian canal at the upper edge.

This is most fortunate at the present moment when thousands of soldiers are returning to our hospitals with injuries to the bones that urgently call for radical operative treatment before the men can be fitted to return to useful civilian life.

CHANGES IN TRANSPLANTED BONE

The experiments on which we have based the principles that have guided our operative work have been spread over a period of the past four years, but with the exception of two short preliminary reports, the results have not yet been published. The conclusions deduced from these experiments may be thus outlined:

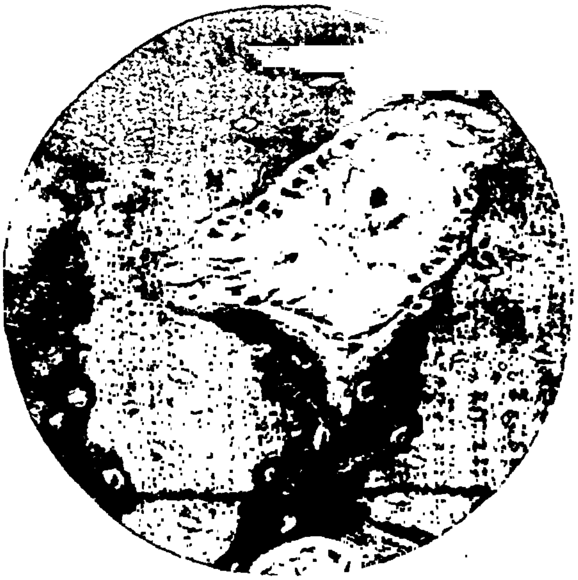

Fig. 2.—High power photomicrograph of one of the cavities shown in Figure 1. It shows the remains of dead cells in the lacunae, the active absorption of the dead bone by the osteoblasts, and the production of new bone in the older portions of the cavity.

When a piece of living bone has been separated from its circulation and implanted elsewhere in the body of the same patient, the immediate result, as indicated in specimens recovered within a few days of the operation, is the coagulation of all cells and vessels to which the surrounding lymph is unable to percolate. This means the death of all the cells in the lacunae and most of those in the haversian canals. This is indicated by the immediate change in the staining property of the protoplasm and nucleus, and is later proved by the complete absorption of these structures after the lapse of from three to four weeks. On the surfaces of the graft and in the open mouths of the haversian canals, however, are many osteoblasts which are in a position to absorb nutriment from the bathing lymph, and these cells are capable of living and proliferating and of producing those changes that make the autogenous graft so valuable in reparative surgery. At the end of the first ten days after the implantation of the graft, the proliferation of these osteoblasts is well established on the periosteal and endosteal surfaces, and within a few days new bone formation can be plainly seen on these surfaces. In addition to forming new bone about the transplant, these proliferating osteoblasts proceed to attack the dead bone of the grafts and rapidly produce excavations about the edges which are at first filled with proliferating cells and later by new bone laid down by these cells on the walls of the excavation (Fig. 1).

While these changes are occurring on the surface, a reestablishment of the circulation has been taking place as the result of the ingrowth of new blood vessels into the mouths of the haversian canals. This proceeds with extraordinary rapidity, and in small, porous transplants is complete in approximately two weeks. Along with these blood vessels the osteoblasts spread inward from the surface, and at the end of three weeks the same changes that have been described on the surface are occurring within the substance of the bone. At first, cavities are excavated along the course of the haversian canals, not far below the surface of the bone. Later this cavity formation, which appears to be a solution of the bone by a secretion from the proliferating osteoblasts, spreads deeply into the transplant until ultimately the whole graft is permeated by blood vessels and osteoblasts that are occupied in the absorption of the dead bone. A few days after the formation of a cavity by these proliferating osteoblasts, the older cells return to their adult function of bone production, and soon the older part of the cavity becomes lined with a layer of new bone. This layer increases in thickness, and trabeculae develop from wall to wall until the whole cavity is filled with living cancellous tissue except in those areas in which the proliferating cells are continuing the work of excavation (Fig. 2).

The rapidity with which these changes occur depends on three factors: the size of the graft, its density, and the abundance of the supply of osteoblasts that survive on the surface. Thus in very thick grafts the absorption and replacement of the dead bone in the depths of the graft is necessarily slow, owing to the distance the new blood vessels and osteoblasts have to travel; and in such cases months must elapse before replacement can occur. The density of the graft is important also, replacement being necessarily slow in hard, dense bone, such as the crest of the tibia, whereas it is very rapid in open, cancellous bone, such as a rib. This is largely due to the mechanical difference in the permeability of the two types of bone and to the difference in the amount of work to be performed to complete the replacement. Of the

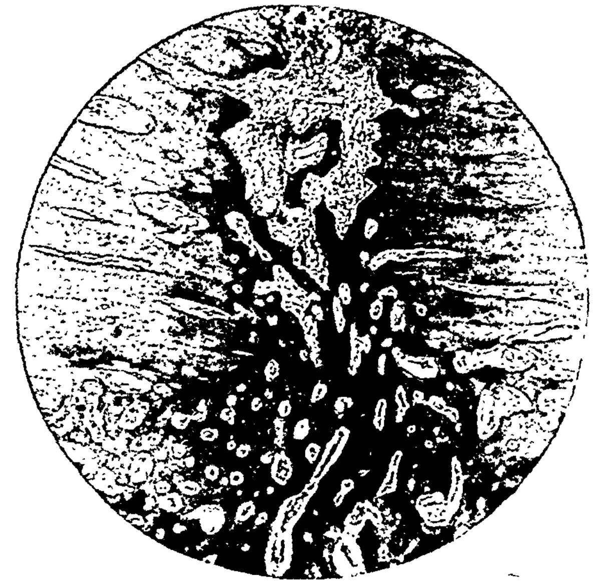

Fig. 3.—Low power photomicrograph of two grafts placed end to end in the bed from which they had been cut. The right hand graft was boiled for ten minutes before being placed. Section made three weeks after operation. It shows that the changes following the implantation of autogenous and boiled grafts are in many respects *identical*. Thus, it shows the reestablishment of circulation in each, the union of each to the underlying cancellous bone, and the absorption and replacement of each by the activity of the invading osteoblasts.

have detected a delayed blood sugar curve in cretinism, myxedema, acromegaly and muscular dystrophy. It has also been recorded by others for acromegaly.[16] It is to be expected, therefore, where other hypoglandular conditions exist. This is a very interesting observation, for it would naturally be expected that the lower the blood sugar level the more quickly the ingested sugar would be removed from the blood. This tendency to a delayed tolerance curve may be taken as an indication that carbohydrate metabolism is disturbed in hypofunctional activity of the endocrine organs. A hyperglycemic response and a delayed blood sugar curve have been observed by us in all cases of hyperthyroidism and exophthalmic goiter tested. This evidence of imperfect carbohydrate assimilation suggests that dysfunction rather than hyperfunction of the thyroid is the underlying condition in exophthalmic goiter. The delayed curve is much more valuable than hyperglycemia in this condition, for certain cases of hyperthyroidism exhibit the former in the tolerance test, yet the fasting blood sugar is normal or subnormal.

The test here suggested unfortunately is of no aid in the differential diagnosis of endocrine diseases in the absence of specific clinical symptoms, for the disturbances of carbohydrate metabolism detected by it are caused by various dysfunctionating ductless glands.

In the first part of the article it was mentioned, in regard to an upper limit of glucose tolerance, that such a condition has been doubted to exist, since normal persons could take increasing amounts of glucose without the appearance of glycosuria. A few grams of sugar, however, usually do appear in the urine of such individuals when very large quantities of glucose are ingested. Increased sugar tolerance with absence of glycosuria has been frequently reported in hypofunctional endocrine disturbances, such as hypophysial dystrophy, in which condition even 500 gm. of glucose have failed to cause glycosuria. The blood sugar tolerance test affords interesting insight into the nature of the increased tolerance thus observed, for it is here that we detected hypoglycemia, which in all probability is the cause of the increased tolerance thus observed. Sugar tolerance tests[17] performed by us on thyroidectomized dogs never showed as great a rise in the blood sugar following ingestion of glucose as did normal animals similarly examined. It is evident from this that more glucose can be assimilated in the case of the athyroid animals without causing glycosuria, and that this is probably due to the fasting low blood sugar level in these animals. As already mentioned, there is a tendency to a delayed sugar curve in these conditions; but this tendency is *never sufficient* to produce *hyperglycemia* and glycosuria, the hypoglycemia being the controlling factor

CONTRAINDICATIONS TO THE BLOOD SUGAR TOLERANCE TEST

Contraindications are irritable stomach in neurotic conditions and grave gastro-enteric diseases when delayed absorption might interfere with the results. Gastrectasia, atrophy of the mucosa, extensive ulcerations, or adhesions preventing normal peristalsis can conceivably affect the absorption rate and invalidate the test.

ADDITIONAL NOTE

The blood sugar tolerance test has been in use at the Montefiore Home and Hospital for the past two years. It was first discussed in a paper[12] read before the Society for Experimental Biology and Medicine, Feb. 21, 1917. Dr. Hamman has kindly called our attention to a preliminary report[18] of his work with Hirschmann on the same subject, read May 10, 1916, before the Association of American Physicians, appearing in March, 1917. We regret that these important data came to our notice after this paper had been written and cannot be conveniently incorporated in the text. Our detailed technic was described in this paper[19] read before the Society for Experimental Biology and Medicine, Nov. 21, 1917.

Nov. 17, 1917, a splendid article by Hamman and Hirschmann[20] appeared, reporting practically the same results as obtained by us.

THE TRANSPLANTATION OF BONE

W. E. GALLIE, M.D.
AND
D. E. ROBERTSON, M.D.
TORONTO

During recent years the science of bone transplantation has been occupying the attention of orthopedic surgeons to a steadily increasing degree. While the earlier operations were pure experiments attended by success or failure, depending on whether the surgeon chanced to employ the principles that are essential to success, the mass of evidence now at hand as the result of experimentation on animals has clearly outlined these principles and placed the clinical employment of the procedure on a sound scientific basis.

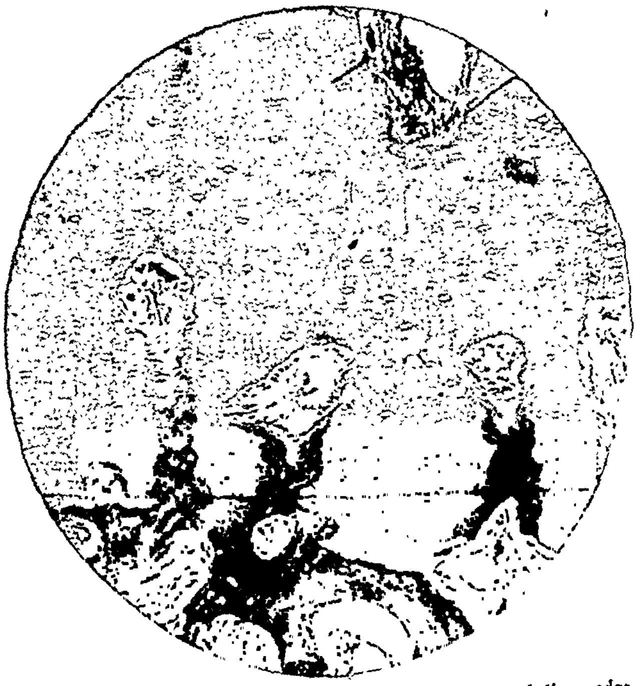

Fig. 1.—Low power photomicrograph taken at the medullary edge of an autogenous bone graft, three weeks after operation. It *shows* the union of the graft to the cancellous medullary bone; the *invasion* of the graft by the *proliferating* osteoblasts, large cavities being formed in its substance; the laying down of new bone on the walls of *these* cavities; the disappearance of the cells from the lacunae, and the reestablishment of the circulation as seen in the large *haversian* canal at the upper edge.

replacement of the graft must depend on osteoblasts from elsewhere. Neither will heterogenous bone fill the requirements, as we have established experimentally that all the cellular elements of bone transplanted from one species into another disappear and leave the graft in a condition similar to that of one that has been boiled. Thus, when gaps in the long bones are to be filled, only the autogenous graft should be employed, as here we have a condition in which contact for the graft can be secured only at the extremities, and consequently the replacement of the central portions of the transplant must depend on living osteoblasts on the surface of the graft itself. If a large gap were bridged by heterogeneous or boiled bone, union would occur at the two ends, in all probability; but the central portion, having no living elements, would slowly absorb and disappear under the action of the body fluids and giant cells. Again, in the treatment of nonunion in fractures, the autogenous graft is essential, because here we are dealing with fragments of bone in which osteoblastic activity is at a minimum.

It is necessary, therefore, to supply living osteoblasts in the largest possible quantity if we are to feel assured of success from operation. Bearing in mind that in these cases we are trying to supply the largest number of living osteoblasts, we should remember that it is only on the surfaces that living osteoblasts survive. It is wise, therefore, to cut the grafts in such a manner that the largest possible osteoblast-bearing surface is exposed. The grafts are cut, accordingly, when the tibia is used, from the face of the bone, not from the crest, the width of the graft being made greater than its thickness. The graft always includes the whole thickness of the bone in order that the endosteal surface, which bears the greatest number of free osteoblasts, may be retained. The old idea that it is better to cut a graft from the solid crest of the tibia rather than from its more porous internal surface is completely refuted by these experiments. In fact, it is much better to avoid the tibia altogether, if strength of the graft is not an essential, and to use a rib that has been slotted so as to expose the endosteal surface to a supply of lymph. The amount of bone regeneration that occurs from the surface of a transplanted rib is much greater than that which occurs from one of the long bones. Further, it is wiser to split the graft longitudinally into a number of pieces rather than to insert it in a single piece, as by this means more surface is exposed and more osteoblasts will survive. In operating for an ununited fracture in a long bone, it is our custom, therefore, to insert a single graft that will be strong enough to fix the fragments and then to fill in around it with a number of smaller strips of bone. The result is a great mass of callus which will aid materially in the union of the fracture.

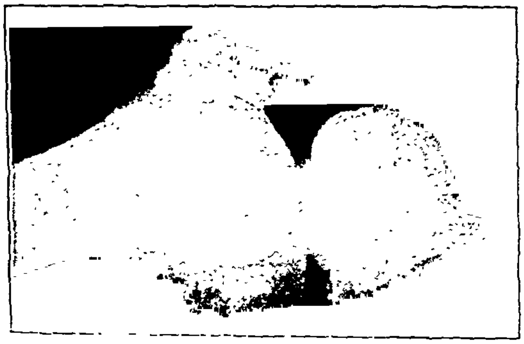

Fig. 8.—Roentgenogram of fracture of patella treated with long boiled bone screw, taken through plaster. The fixation is excellent.

Here the vexed question of the periosteum presents itself. Some years ago we presented a paper on the subject before the Canadian Medical Association in London, consisting of a report of a series of experiments based on the work of Macewen. The results of these experiments agreed completely with those of Macewen, indicating that the periosteum as viewed by the surgeon is only a limiting membrane composed of fibrous tissue, and that the great majority of the subperiosteal osteoblasts cling to the bone when the periosteum is removed. This view has been further substantiated by a series of experiments in which bone was transplanted with and without periosteum into the muscles of the back, and the amount of osteogenetic activity on the periosteal surface compared. These experiments showed that the value of the graft from the standpoint of osteogenesis was the same in the two cases. We are therefore in the habit of transplanting the bone without its periosteum, using the reflected periosteum to cover up the space left by the removal of the graft.

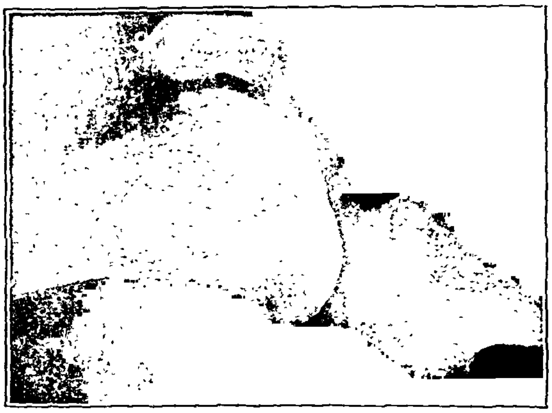

Fig. 9.—Roentgenogram of fracture of patella after lapse of six months. Note union of fracture and absorption of screw. Function normal.

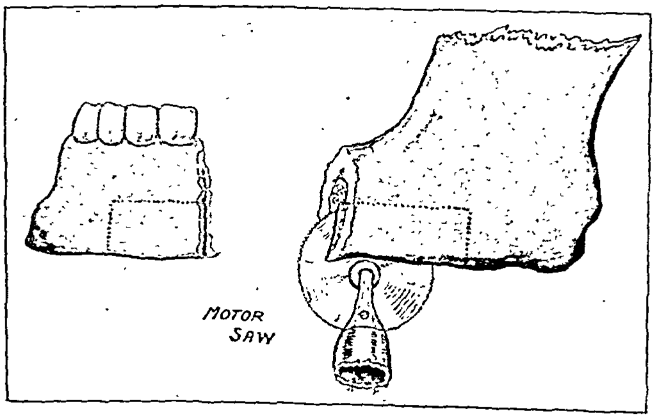

Fig. 10.—Application of motor saw in operation for closing gap in mandible produced by gunshot wound.

While the types of cases described above demand the use of the autogenous graft, there are others in which the element of fixation is the principal object of the operation and in which the boiled graft has several decided advantages. In previous papers we have described the use of boiled plates and screws used to replace the metallic splints described by Lane. The first experiments were performed on dogs, and consisted of the production of fractures and the fixation of the fragments with plates and pegs of boiled bone. The specimens recovered at intervals after the operation showed the rapid union of the fracture and union of the plate and pin to the underlying bone. At the end of two months the union of the dead to the living bone was perfectly solid, and microscopic examination showed the changes described above, namely, the establishment of a circulation, the laying down of new bone on the surface of the plate, and the process of replacement of the dead bone by the living bone of the animal. At the end of six or eight months, all signs of the plate had disappeared, the only indication of it being a slight fusiform swelling of the shaft, which also disappeared in time (Fig. 4).

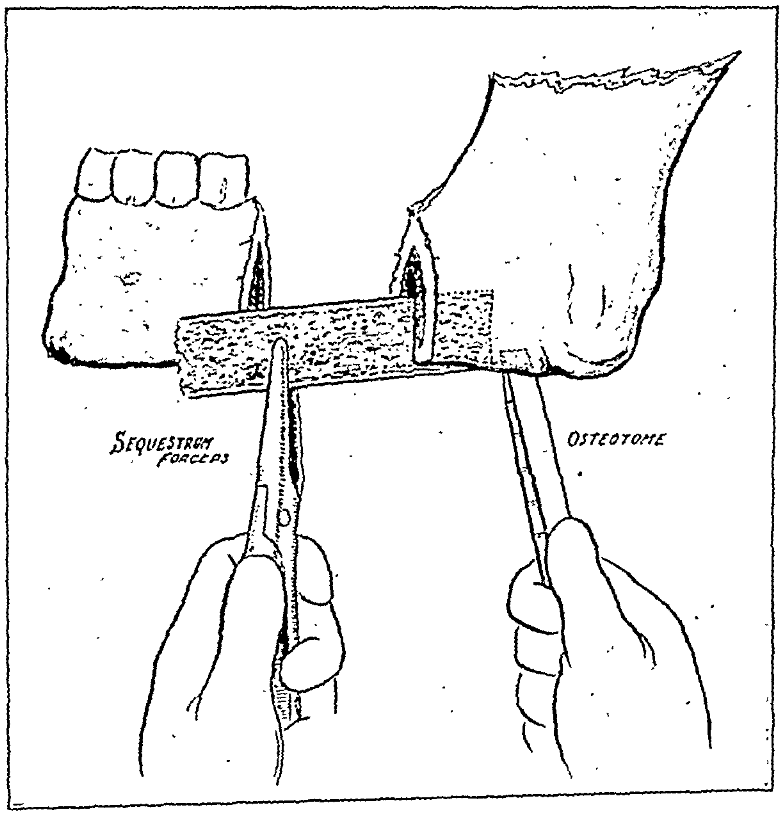

Fig. 11.—Insertion of half of split rib with smooth side toward the mouth cavity.

RESULTS OF BONE TRANSPLANTATION

These experimental findings were immediately applied in clinical cases, and a series of recent fractures of the femur were treated by open operation, the fixation being secured by the use of plates and screws made from boiled bone (Figs. 5, 6 and 7). The results in these cases have proved highly satisfactory, and the method is being applied by ourselves and our colleagues in all cases in which it is deemed advisable to do an open operation on a fracture. The advantage of this method over the Lane technic is obvious, as no foreign material that is apt to get loose or produce late irritation is introduced. The union of the plate to the living bone and its ultimate absorption are decided advantages, as the bone plate thus combines the valuable points of the metal plate and the heterogenous graft. The advantage of the boiled plate over the autogenous graft rests in the fact that the plates can be made in any suitable shape before the operation, and no second incision or mutilation of the fragments is necessary to secure a graft. Recently the use of the boiled screws has been extended to the operative treatment of oblique fractures of the long bones and to fractures of the patella and olecranon, long screws being used without the application of any plate. The results have been very satisfactory (Figs. 8 and 9). As pointed out in previous papers, this employment of boiled bone is not new, as many writers have referred to its more or less successful use; but the experiments referred to above place the principle on a scientific basis and limit its use to those cases in which it is certain to be of value.

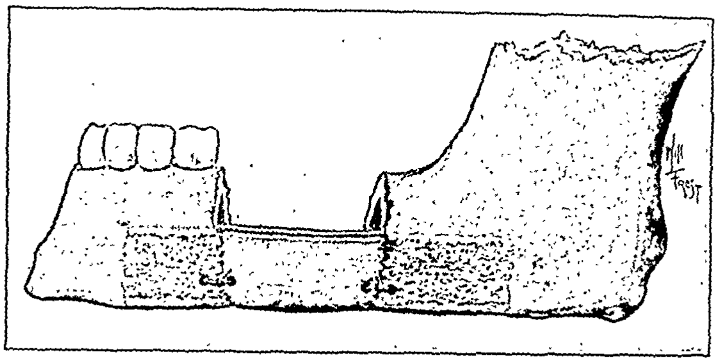

Fig. 12.—Completion of operation by the placing of the other half of the rib in contact with the first half, between the ends of the fragments, and by the fastening of all in place with kangaroo tendon.

At a recent meeting of the American Orthopedic Association, one of us reported the employment of boiled bone in four cases of Pott's disease of the spine. The operation was first performed on a dog, and as it appeared satisfactory, the experiment was extended to four children. The grafts were prepared beforehand, of the correct size and shape, from beef and dog bone, and boiled with the instruments. These boiled grafts were then solidly implanted into the split spines or about the spines from which the periosteum had been removed. Primary union occurred in all the cases, and clinically each case has progressed much as after the autogenous graft. The operations were performed more than two years ago, so that sufficient time has elapsed to allow of the expression of an opinion on the success of such a procedure. The roentgenograms taken at intervals show the solid union of the graft to the spines and the gradual rounding off of the edges and lessening of its density until it appears to exist simply as a fusion of the tips of the spines, much as the ordinary autogenous graft appears after the lapse of a year or more. Fortunately, it was possible to obtain a small piece of one of these grafts two years after it was inserted, and microscopic section of it shows complete disappearance of the dead bone and its replacement by strong trabeculae of living tissue. Over its surface is a perfectly normal periosteum.

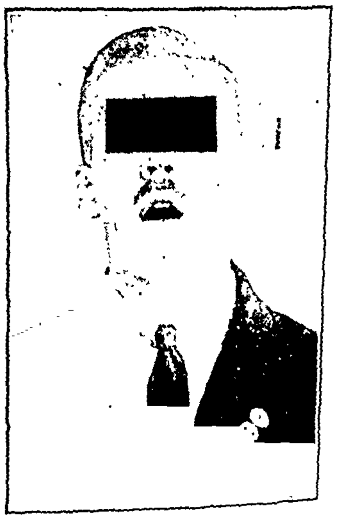

Fig. 13.—Soldier on whose jaw operation was performed; range of motion of jaw normal.

If experience upholds the apparent success of these four cases, the value of the technic is obvious. The autogenous spinal graft operation calls for a second incision over the tibia and an extensive removal of bone for the making of the graft, whereas the use of boiled bone eliminates the necessity for the second operation.

Our clinical experience has now extended over a long series of cases of bone transplantations. It includes a series of sixty cases of Pott's disease in which the spinal graft operation was performed, sixty cases of nonunion and malunion in fractures in which the autogenous transplant was used, and sixty or more cases of open operations on recent fractures in which boiled bone plates and screws or screws alone were employed. In addition, a number of odd operations were performed which will be described later.

The spinal graft operation is of undoubted value. Necropsy specimens, of which we have two, obtained a year or more after the operation, show the solid fusion of the spines. Clinically, these patients are improved by the fixation given to the spine, and as a result they can be allowed on their feet earlier. Increase in the deformity is more successfully prevented by this means than by any other. We employ it in all suitable cases. Just how far the technic as described by Albee will be replaced by the boiled bone method cannot be estimated until further clinical evidence is obtained.

In the open operations for nonunion we favor the inlay graft as described by Albee, although occasionally we have employed the medullary plug. The former appeals to us as the better method, as it opens up the medullary canal well back from the diseased area and allows the outflow of healthy osteoblasts from the fragments themselves. The failures following the medullary plug method are probably due to the plugging of the canal and the prevention of the outflow of osteoblasts. We make it a practice to drill holes and make saw cuts in the ends of the fragments to stimulate the inflammatory reaction necessary to osteogenesis. In addition, all fragments of cancellous or endosteal bone that can be picked up are strewn around the graft in order that the supply of living osteoblasts may be at a maximum. The graft should be extended well beyond the sclerosed bone of the ends of the fragments, and is usually 4 or 5 inches in length.

In certain cases of nonunion in which it is difficult to obtain perfect fixation of the fragments by the inlay method, we have used another technic which has proved satisfactory. Thus, in fractures of the tibia and of the humerus, the fragments sometimes have a strong tendency to slip sideways, and one does not feel that the kangaroo tendons that hold the inlay in position are strong enough to be trusted. In such cases, after the proper preparation of the ends of the fragments, a section of rib, 3 or 4 inches in length, is removed subperiosteally, and by means of an osteotome is split longitudinally on the flat into two plates, each of which has an endosteal surface. One of these plates is cut into strips, and these are used as medullary grafts, care being taken that the medullary cavity is not tightly plugged. The surface of the fragments is then freshened and flattened with an osteotome, and the other half of the rib applied as a bone plate, two or four bone screws being used to hold it in place. The medullary surface of the rib being applied to the freshened surface of the fragments, the union of the rib to the fragments is rapid and the advantage of the autogenous graft secured. The fixation afforded is excellent. This technic is also valuable in ununited fracture of the patella, the split rib being sunk into the anterior surface of the bone across the line of the fracture, after the ends have been freshened, and fastened with bone screws.

Amid all the enthusiasm at present surrounding the employment of the bone graft in the treatment of nonunion in fractures, it must be recorded that failures are frequent. In the past few months we have seen in our military orthopedic clinic half a dozen cases which have been complete failures, owing to disregard for the principles which must be employed to insure success. The chief error in military surgery has been that the bone graft operation has been performed too soon after the healing of septic gunshot wounds which produced the fracture. The result has been the immediate setting up of suppurative inflammation with the extrusion of the graft and the production of renewed osteomyelitis. In these cases, operation must not be performed until six months or more have elapsed after the complete disappearance of all inflammatory phenomena. The next most frequent error has been the attempt to bridge gaps in the bone by the use of short, strong grafts cut from the crest of the tibia. As pointed out above, such grafts show the minimum of osteogenic activity, and in reality are little better than boiled bone, which, of course, would be useless. The grafts must be long and well set into the fragments, and placed in contact with healthy bone; otherwise union of the graft to the fragments will not occur. Further, the graft must be as porous as the requirements of strength will allow, and as many small pieces of osteoblast-bearing bone as can be found must be introduced. For very bad sclerosed fractures we use a tibial graft to provide strength and strips of rib to supply the osteoblasts. In addition, we doubt very much the wisdom of attempting to bridge gaps at all in many cases, recognizing as we do the great difficulty of securing union under any circumstances. It is better to accept a certain amount of shortening, and get the freshened ends of the fragments in good contact before inserting the graft, than to take the additional chances of a failure to get union.

On the other hand, if one performs the operation with due regard to the principles enunciated, success may be anticipated in the majority of cases. We have been able to get good bony union in cases of fracture of the tibia in which nonunion had been present for as long as twelve years.

OPERATION ON THE JAW

In the fracture of the mandible in which it is essential that gaps shall be bridged in order that deformity of the jaws may be avoided, the technic used in our clinic is as follows (Figs. 10, 11 and 12):

The fragments are exposed by a long incision along the lower border of the jaw. The motor saw is then applied to the fragments, and a saw cut made along the inferior border extending an inch to an inch and a half back from the end of the fragment and about half an inch deep. Great care must be taken to avoid opening into the cavity of the mouth or into the sockets of the teeth. An osteotome is then driven into the saw cut, and a greenstick fracture produced, widening the wedge-shaped gap for the reception of the graft. An interdental splint which has previously been cemented to the teeth of both jaws is now l[illegible] with the teeth of the two jaws in exactly the co[illegible] to one [illegible]ther. The graft is made b[illegible] of a rib[illegible] piece of rib is then [illegible] that the [illegible] face may be [illegible] graft i[illegible] into the slots in the fragments, the smooth side of the rib facing toward the mouth cavity. This leaves the rough, cancellous surface of the graft facing outward and sunk somewhat below the outer surface of the jaw. This depressed area is then filled out by laying a piece of the other half of the rib in the gap, with the smooth side out. The fragments and grafts are now fastened solidly in place with kangaroo tendon passed through drill-holes. This adds additional security although it is really unnecessary, as the principal graft is self-retaining, being wedged solidly into the saw cuts in the fragments.

The operations on the jaws have been most satisfactory. Several soldiers have been operated on in our clinic who have been able to eat ordinary food five months after the implantation of a graft which has bridged gaps of from 1 to 2 inches (Fig. 13).

BONE TRANSPLANTATION IN WOUNDS OF THE FACE

Occasionally the transplantation of bone is of value in cases of wounds of the face in which permanent openings into the sinuses of the nasal cavity have been produced.

During the past year a patient was operated on by Dr. Edm oyd and one of us, in whom there had been a com- ion of the bridge of the nose, leaving a perma- about the size of a 25-cent piece leading into ells. This opening was surrounded by a very ar. The operation was performed in three stages. st stage the septum of the nose was straightened the fragments of the nasal bones, which had been en inward, were removed. At the same time a section of rib was emoved and split as described above and placed u of the dorsum of the forearm, superficial to At the end of three weeks the edges of the ce were dissected free of scar and the nasal frontal bone freshened with a chisel. A flap was then raised from the forearm, includ- uried bone graft and the deep fascia, and the edge s flap sewed to the edges of the gap in the forehead. e end of the graft was exposed and placed in contact with the frontal bone, in fact, driven into it. The head and arm were then encased in plaster of Paris and the wound left undisturbed for three weeks. The flap was then freed from the forearm and accurately sewed to the remainder of the opening in the face. Healing occurred kindly, and the whole flap retained its vitality. A small sinus closed after discharging six weeks. This patient now has a complete closure of the unsightly hole in his face, and the anterior wall of his ethmoidal sinuses is protected by a solid plate of bone.

CONCLUSIONS

We wish to draw attention once more to the principles that should govern the science of bone grafting. It must be remembered that a so-called living autogenous bone graft is alive only in virtue of the osteoblasts that are free on its surfaces, and in the mouths of the haversian canals. All the rest of the graft dies and is absorbed. It owes its value in bridging gaps and in encouraging union of ununited fractures to the fact that during the process of its absorption the osteoblasts which invade it from its own surfaces and from the neighboring bones build up new bone to take the place of that which is absorbed, so that ultimately the break in the continuity of the injured bone is bridged by new and healthy bone. This established fact indicates at once the necessity for perfect contact of the graft to fresh, healthy bone in the fragments, and shows the reason for extending the graft well beyond the sclerosed extremities. It also shows the importance of using, as a graft, bone from which the periosteal and endosteal surfaces have not been removed, as it is on these surfaces that the greatest number of osteoblasts is to be found.

For the same reason the graft should be made from bone which is as porous as the requirements of the case, in relation to strength, will allow. Hence the value of the rib as a graft, particularly if it has been opened up so that the osteoblasts of the interior can obtain the necessary supply of lymph.

After the principal graft has been inserted, as many small pieces as possible should be packed around it, the fragmentation increasing the surface area exposed and hence increasing the number of surviving osteoblasts.

In those cases in which the introduction of living osteoblasts is not an essential feature of the operation, the value of boiled bone must not be overlooked, as it possesses many of the virtues of the autogenous graft without some of its disadvantages.

AN OCCASIONAL TYPE OF LOUD SYSTOLIC MURMUR IN CARDIOSCLEROSIS

SELIAN NEUHOF, M.D.
Visiting Physician, Central and Neurological Hospital; Adjunct Attending Physician, Lebanon Hospital
NEW YORK

By cardiosclerosis, I refer to marked pathologic changes involving the cardiac muscle, the valves, the aorta, and involving the coronaries and their branches. The damage is rarely equally distributed among these structures. Frequently the aorta and coronary system are the most affected.

Although the auscultatory phenomena to be described are more often present in the senile, the middle-aged are also occasionally affected by a cardiosclerotic process which produces physical signs exactly as in the aged.

The senile cases of this type possessed all the usual characteristics of marked generalized arteriosclerosis: thickened, palpable and tortuous arteries, usually a slight increase in the systolic blood pressure, and a trace of albumin and a few casts in the urine. Cardiac failure was sometimes, though by no means invariably present. As demonstrated by the physical examin tion and corroborated by roentgenograms, the card area was enlarged. Pulsation of the aortic arch usually well marked; this could be demonstrate insinuating the finger, or the bell of the stethosco the interclavicular notch behind the manubrium.

Of extreme interest were the auscultatory nomena. Over the entire anterior aspect of th a loud, rough systolic murmur was heard, its greatest intensity being at the right base a lower precordium. The murmur was someti mitted along the carotids and to the lower spaces in the axillary line. In addition, it sionally transmitted as a muffled or faint sy posteriorly in the interscapular region, louder on the right than on the left side.

The complex is well exemplified by th cases:

REPORT OF CASES

Case 1 (History 3530).—C. L., a man, age from moderate dyspnea at the time of hospi The systolic blood pressure was 130; the diast urine contained a trace of albumin. The cardiac rhythm was normal, the rate between 76 and 80 per minute. Over the entire middle anterior aspect of the chest, there was heard a loud, rough systolic murmur transmitted slightly to the left axilla and along the carotids. The roentgenogram revealed an aortic arch almost twice the normal width, and a somewhat enlarged left ventricle. The patient was put on digitalis medication; he left the hospital one week later; the dyspnea was considerably improved.

Case 2 (History 3074).—M. C., a woman, aged 64, complained of cough and dyspnea. Six months prior to hospital admission, she suffered from some precordial distress, the exact nature of which could not be determined. The temperature was 102; there was moderate dyspnea, and there were signs of general bronchitis. The fever and bronchitis lasted two weeks. The cardiac area was somewhat enlarged on percussion; a loud, rasping, systolic murmur was heard over the entire precordium; it was especially intense over the right base. The murmur was transmitted along the carotids and laterally to the left axilla. It was also heard as a muffled systolic bruit posteriorly in the upper interscapular region. The systolic blood pressure was 220; the diastolic, 140. The urine contained a moderate amount of albumin and some hyaline casts. The roentgenogram revealed not only slight dilatation of the aortic arch but also aneurysmal dilatation of the entire descending thoracic aorta. The latter was a prominent shadow in the left side of the chest from the second to the fourth left interspace; at that point it became lost behind the shadow of the left ventricle. The characteristics and physical signs of aneurysmal dilatation of the thoracic aorta I have already reported.[1]

Case 3 (History 3463).—J. M., a man, aged 66, complained of epigastric pain, dizziness, headache and some dyspnea. There were old syphilitic (?) scars on the forearm. The lungs appeared normal. Over the entire precordium there was a loud, rough systolic murmur. The cardiac area was somewhat enlarged to percussion. A roentgenogram revealed moderate enlargement of the aortic arch. The cardiac rhythm was normal. The systolic blood pressure was 135; the diastolic, 95. The urine contained a slight trace of albumin.

The middle aged individuals with cardiosclerosis and loud precordial systolic murmurs often present an unusually robust appearance. Indeed, until examined, one would scarcely suspect such striking contrast between evident extreme pathologic changes in the heart and the apparently healthy looking patient. This group is typified by the following examples:

Case 4.—C. H., a woman, aged 50, buxom in appearance, has had three children, and no miscarriages. For years she suffered from severe rheumatic (?) neuralgic headaches. For one year, she had had precordial oppression and attacks of severe precordial pain radiating to the jaw, the back, and the left arm. A rest cure lasting several weeks brought no relief. The blood Wassermann was negative. The systolic blood pressure was usually about 170; the diastolic, 110. The nonprotein nitrogen and other constituents of the blood were normal in amount. There was no dyspnea when at rest. On palpation, slight overaction of the carotids and of the aortic arch was noticeable. Over the right base, there was a loud, rough systolic murmur transmitted along the carotids; it was also heard posteriorly in the middorsal region to the right of the spine; below, it became less intense and merged with an extremely loud systolic murmur which was most prominent and distinct over the mitral area. The orthodiascopic tracing revealed an enlarged aortic arch and a somewhat globular and enlarged left ventricle. The patient died a few months later in an attack of edema of the lungs.

Case 5.—A. B., a physician, aged 54, of vigorous appearance, contracted nephritis following a grip infection about twenty years previously. Cardiac complaints began about four years before I saw him. They at first consisted of occasional hemoptysis and of slight dyspnea. Of late months the dyspnea had increased, and was accompanied by a sense of weight on the chest. The Wassermann blood reaction was negative. The apex beat was diffuse. Over the entire anterior aspect of the chest, there was heard a loud, musical systolic murmur, most intense over the right base and the lower precordium; it was least intense over the midsternum. It was transmitted along the carotids, and was also heard posteriorly at the third dorsal vertebra. The orthodiascopic tracing revealed an enlarged aorta and a hypertrophied left ventricle. The patient died a few months later of edema of the lungs.

The most striking characteristic of these cases — both in the senile and in the middle-aged — is the loud rough systolic murmur heard over a large portion of the anterior surface of the chest. At a casual examination, one might ascribe the murmur to the presence of a large sacculated aneurysm or to aneurysmal dilatation of various parts of the aorta. Both types of aortic enlargement, however, are usually accompanied by diastolic, as well as systolic murmurs, the area of greatest intensity being over the right base of the heart. In aneurysmal dilatation of the descending thoracic aorta,[1] I have found the double murmur loudest in the third left interspace near the sternum; from this location, it tailed away toward the apex and base. In cardiosclerosis, when the loud systolic murmur was heard with or without aortic enlargement, a diastolic murmur was absent. In addition, careful auscultation revealed a marked difference in the intensity of the murmur over the precordium. It was very loud over the right base, losing in intensity over the midsternum, again becoming louder at the cardiac apex and to the left. It thus seemed as if the murmur were made of two components—an aortic and a mitral. The former was probably caused by such arteriosclerotic changes as deformities and thickening of the aortic cusps, and calcareous deposits and thickening of the wall of the aorta. The mitral component of the murmur may be ascribed to the characteristic degenerative changes affecting the mitral valve and the mural endocardium of the mitral ring, with the consequent production of a typical mitral regurgitant murmur. The aortic and mitral components are both systolic in time; hence, when the pathologic changes are of the gross nature above outlined, a loud systolic murmur results which may be of fairly equal intensity over the entire front half of the chest, or there may be an area of less distinctness and intensity over the midsternum.

1275 Madison Avenue.

Patent Medicines.—Death has lately claimed two Americans whose works or whose name and physical presentment were intimately familiar to unnumbered millions of their countrymen. About a fortnight ago there passed away at Columbus one S. B. Hartman. He gave Peruna to civilization. On Sunday there died at Palm Beach one James M. Munyon, whose uplifted index finger had for its only rival in popularity the somewhat similar gesture of the Statute of Liberty in New York Harbor. It is not recorded that either of these men died of a broken heart, or that an autopsy would have revealed, inscribed on that organ, the words "Pure Food Law." Yet there is a certain tragic coincidence in the fact that the disappearance of these two men should have come at a time when prohibition is swarming over the top for the final charge. It is the climax of a campaign which began with the capture of the first-line trenches several years ago, when Peruna and its allies, the various bitters, malt whiskies, wines of life and reinforced sarsaparillas were thrown definitely on the defensive or altogether swept out of existence. Another year or two and most of these giants of the advertising columns will be forgotten. Their fame was writ in equal parts of water and alcohol.—New York *Evening Post.*

VACCINATION AGAINST EXPERIMENTAL POLIOMYELITIS

PRELIMINARY NOTE *

H. L. ABRAMSON, M.D.
NEW YORK

Efforts leading to the development of a practicable method for protection against acute poliomyelitis have thus far been very poorly rewarded.

Flexner and Lewis,[1] in 1910, showed that monkeys could be immunized against poliomyelitis by repeated subcutaneous injections of increasing amounts of crude unmodified virus over a period of two and one-half months. These animals, after a further ten days, were injected intracerebrally with 2 c.c. of a filtrate of a highly potent virus, of which from 0.05 to 0.1 c.c. would prove fatal. The immunized animal therefore resisted from twenty to forty fatal doses. In a later report, they state that artificial active immunity either by the injection of a single large dose or by a series of increasing small doses of crude virus over a period of time is not uniformly successful. In the former method, some of the animals developed poliomyelitis as a result of the subcutaneous injection, and in both, some of the animals so injected did not resist the test intracerebral inoculations of the rather large dose of a highly potent virus.

Levaditi and Landsteiner[2] dried cords from monkey poliomyelitis after the method of Pasteur for rabies, but they found that some of the animals developed poliomyelitis as the result of the preventive inoculations.

In this communication I shall report the results of efforts toward the practicable utilization of facts established by the authors mentioned.

To be of practicable value, a method of artificial active immunization should have the following requisites:

1. The method should protect against any reasonable exposure to the disease for which the individual is inoculated.
2. The inoculations in themselves should be harmless.
3. The method should not be too cumbersome or prolonged, so as to render production of immunity too slow to be of practical value.

We have attempted to comply with these conditions. The material used is crude monkey virus of the highly virulent Rockefeller strain. The virulence of this strain in 1910 was such that from 0.05 to 0.1 c.c. of a filtrate of a 5 per cent. emulsion was lethal for the *Macacus rhesus.* This strain had been passed through many additional monkey generations when we obtained it, about eighteen months ago, and in our hands has been passed through ten additional generations. The method employed in this work consists of the daily subcutaneous injection of this virus, either brain and cord or cord alone, in 10 per cent. saline emulsion on five successive days. The material used on the first four days is modified by heat. The final injection is made up from either the fresh or glycerolated material unheated. The material of the first two injections is subjected to 55 C. for one-half hour; of the third injection, to 45 C. for one-half hour; of the fourth, to 37 C. for one-half hour; the fifth is unmodified by heat. Twenty days after the last injection, the animals are bled from the heart for the purpose of determining the presence or absence of neutralizing substances. On the following day, the "immunized" animals and normal controls received from three to six intracerebral lethal doses of the highly potent monkey virus. Other animals were inoculated with a mixture of serum obtained by heart puncture from immunized monkeys, and the same virus was used in the test inoculations. This mixture consisted of one part of virus and one of serum, and was exposed to 37 C. for two hours, and to ice box temperature for twenty-two hours. The animals used in these experiments were all of the *Macacus rhesus* variety.

Of eight animals so treated, five have withstood the intracerebral inoculation of from three to six lethal doses. The serums obtained from six of these animals all contained neutralizing principles, but in varying degrees. Two of the serums completely neutralized the virus. The animals receiving these mixtures are alive and well. The remaining four serums prolonged the incubation period to twenty-five, twenty-one, twelve and eleven days, respectively. Four normal control animals showed symptoms in four and five days. A mixture of ten parts of serum and one of virus has been considered a sufficient test to determine the presence or absence of neutralizing substances. It can, therefore, be stated with considerable assurance that serums which can prolong an incubation period of five days from eleven to twenty-five days when used in the proportions of these experiments possess neutralizing substances. Lack of animals has compelled us to apply an unusually severe test. Otherwise we would have made additional tests of the serums in the proportions of ten parts of serum to one part of virus, and five parts of serum to one part of virus, and so have obtained a more definite estimate of the content of neutralizing substances.

The animals treated by this method were subjected to more than a reasonable exposure, as attested to by the effects of similar intracerebral inoculations on the normal controls. These showed symptoms of the fatal disease in four and five days. To indicate further the severity of the test to which the animals were subjected, two monkeys that presented residual paralyses, one of both lowers and the other of the right lower as a result of experimental infections with the virus of the 1916 epidemic, succumbed just as readily as the controls when injected intracerebrally with 1 c.c. and 0.5 c.c., respectively, of the same emulsion used on the treated animals.

According to experienced workers in this field, animals that have recovered from the experimental disease are considered to be highly resistant to reinfection. Yet these animals were reinfected by one-half and one-fourth the dose, respectively, that Flexner and Lewis used in their experiments. Even one minimum lethal intracerebral dose is an unusually severe test from a practical point of view, since by this method of infection the combative forces in the blood of the general circulation are circumvented. In the natural method of infection, the virus would encounter, in persons immunized by such a method as this, a surplus of immune substances in the mucous membranes, and so be neutralized before it could gain access to the central nervous system.

[2] Levaditi and Landsteiner: Compt. rend. Soc. de biol., 1910, 68, 311.

Thus far the method has produced no untoward effects. Eleven animals have been so treated and none have shown any ill results from the injections per se. The attenuated material of the first three injections has apparently produced sufficient immunity to render the animal resistant to the subsequent injections of virus of high virulence.

That this is so was proved by results in four other animals, two of which were injected subcutaneously with crude virus thought to be attenuated by exposure to a weak formaldehyd solution, and two that were injected subcutaneously with virus heated to 50 C. for one-half hour. All of these animals developed poliomyelitis as a result of the subcutaneous injections.

The possibility of harmful effects from the method if applied to human beings is, of necessity, less than when applied to monkeys, since this virus has been adapted to monkeys for the past eight years, and by constant passage through these animals has become highly virulent for the monkey.

The period required for this series of injections is a short one, only five days, which, of course, would render it highly practicable in time of epidemic, when a rapid method is to be desired. Furthermore, it is a simple method. Ordinary laboratory facilities are sufficient for the production of this vaccine. Glycerolated brains and cords of this highly virulent virus can be kept on hand over long periods of time, and the vaccine made up from time to time from this stock as occasion demands.

Further work along these lines is in progress, particularly with reference to the duration of the period of immunity conferred by this method.

THE VALUE OF ROENTGEN RAYS AND BENZENE IN THE TREATMENT OF POLYCYTHEMIA VERA *

SAMUEL H. HURWITZ, M.D.
AND
ERNEST H. FALCONER, M.D.
SAN FRANCISCO

The treatment of that form of polycythemia associated with splenomegaly and chronic cyanosis has not, up to the present time, been entirely successful. In the absence of any exact knowledge concerning the pathology of polycythemia vera, therapeutists have been unable to attack the disease at its source. The treatment has, for the most part, been symptomatic, and the available therapeutic measures have been directed chiefly to the reduction in the number of circulating red blood corpuscles. Such efforts have been well directed, because it seems not unlikely that many of the symptoms of the disease—the headache, vertigo, cyanosis and dyspnea—are in great part attributable to the mechanical stasis in the circulation due to the polyglobulism. And whereas, the therapeutic agents employed have not resulted in permanent cures, they have been effective in reducing the number of circulating erythrocytes, and on this account they merit the attention that has been accorded them.

With this end in view, a number of methods have been tried, such as splenectomy, venesection, the administration of drugs, and the application of various rays either to the spleen or to the long bones.

The removal of the spleen in this disease has usually been fatal within a few days, and the treatment is therefore contraindicated.

Venesection has been employed on the ground that it gives at least temporary relief. But all who have resorted to this measure are now agreed that even if repeated at fairly regular intervals, venesection fails to produce any permanent good effects.

The drug therapy of this affection has been especially inclusive, as nitrites, iodids, bromids, mercury, and a host of other medicinal agents have all been tried. With the exception of benzene (benzol, C_6H_6), however, these drugs have brought about only a doubtful improvement in the clinical symptoms of which these patients complain.

The results reported from the use of the roentgen rays alone are contradictory. Judging from the observations recorded in the literature, the application of roentgen rays has been of marked benefit in some cases, whereas their employment has been unsuccessful in others.

It is our purpose in this report to record the beneficial therapeutic results that have followed the combined use of benzene and roentgen rays in a patient presenting the classical signs and symptoms of polycythemia vera. Although more than a year has elapsed since any form of treatment has been given, the patient's blood still shows a normal number of red blood corpuscles and a normal hemoglobin percentage. Her health continues excellent. The headache and dizziness, symptoms which first brought her under medical observation, have entirely disappeared. There has been an almost complete disappearance of the cyanosis of the facial prominences and extremities, although the lips and mucous membranes still have a reddish cyanotic hue. The improvement in her psychic condition has been marked since she has ceased to be a subject of general interest and curiosity.

REPORT OF CASE

M. D., aged 38, a milliner by occupation, first came under medical observation in April, 1915, complaining of nervousness and dizziness. There had been little illness in her family, and she herself had always been in excellent health. Aside from measles and diphtheria in childhood, she could recall no periods of ill health.

About three or four years before she was first seen, she had had a sudden attack of dizziness lasting only a few minutes, followed by occasional headaches, and in April, 1915, she had been suddenly seized with an attack of blindness, lasting fifteen or twenty minutes.

It was after this last attack that she was examined by Dr. E. H. Julien, who had noted considerable cyanosis of the face, gums, arms and hands. May 18, 1915, a blood count was made which showed a hemoglobin percentage of 105, 12,400,000 red blood corpuscles, and 9,000 white blood corpuscles. A diagnosis of polycythemia vera was made and the patient entered a hospital for treatment. This consisted of a milk diet, frequent intramuscular injections of an arsenical preparation, and venesection. For a period of more than a year, from June, 1915, to August, 1916, venesection was the principal mode of treatment, and she remained comparatively free from subjective symptoms during this period.

In July, 1916, the patient first came under our care.[1] She was found to be well developed and very well nourished, with a dark red face, cyanotic cheeks, and with lips and gums

---

* From the Medical Clinic, University of California Hospital.

* Presented before the meeting of the San Francisco County Medical Society, Feb. 12, 1918.

[1] For the opportunity of following the patient subsequently and for the privilege of carrying out the form of treatment outlined in this report, we are indebted to Dr. E. H. Julien, who kindly referred this patient to us.

VACCINATION AGAINST EXPERIMENTAL POLIOMYELITIS

PRELIMINARY NOTE *

H. L. ABRAMSON, M.D.
NEW YORK

Efforts leading to the development of a practicable method for protection against acute poliomyelitis have thus far been very poorly rewarded.

Flexner and Lewis,[1] in 1910, showed that monkeys could be immunized against poliomyelitis by repeated subcutaneous injections of increasing amounts of crude unmodified virus over a period of two and one-half months. These animals, after a further ten days, were injected intracerebrally with 2 c.c. of a filtrate of a highly potent virus, of which from 0.05 to 0.1 c.c. would prove fatal. The immunized animal therefore resisted from twenty to forty fatal doses. In a later report, they state that artificial active immunity either by the injection of a single large dose or by a series of increasing small doses of crude virus over a period of time is not uniformly successful. In the former method, some of the animals developed poliomyelitis as a result of the subcutaneous injection, and in both, some of the animals so injected did not resist the test intracerebral inoculations of the rather large dose of a highly potent virus.

Levaditi and Landsteiner[2] dried cords from monkey poliomyelitis after the method of Pasteur for rabies, but they found that some of the animals developed poliomyelitis as the result of the preventive inoculations.

In this communication I shall report the results of efforts toward the practicable utilization of facts established by the authors mentioned.

To be of practicable value, a method of artificial active immunization should have the following requisites:

1. The method should protect against any reasonable exposure to the disease for which the individual is inoculated.
2. The inoculations in themselves should be harmless.
3. The method should not be too cumbersome or prolonged, so as to render production of immunity too slow to be of practical value.

We have attempted to comply with these conditions. The material used is crude monkey virus of the highly virulent Rockefeller strain. The virulence of this strain in 1910 was such that from 0.05 to 0.1 c.c. of a filtrate of a 5 per cent. emulsion was lethal for the *Macacus rhesus*. This strain had been passed through many additional monkey generations when we obtained it, about eighteen months ago, and in our hands has been passed through ten additional generations. The method employed in this work consists of the daily subcutaneous injection of this virus, either brain and cord or cord alone, in 10 per cent. saline emulsion on five successive days. The material used on the first four days is modified by heat. The final injection is made up from either the fresh or glycerolated material unheated. The material of the first two injections is subjected to 55 C. for one-half hour; of the third injection, to 45 C. for one-half hour; of the fourth, to 37 C. for one-half hour; the fifth is unmodified by heat. Twenty days after the last injection, the animals are bled from the heart for the purpose of determining the presence or absence of neutralizing substances. On the following day, the "immunized" animals and normal controls received from three to six intracerebral lethal doses of the highly potent monkey virus. Other animals were inoculated with a mixture of serum obtained by heart puncture from immunized monkeys, and the same virus was used in the test inoculations. This mixture consisted of one part of virus and one of serum, and was exposed to 37 C. for two hours, and to ice box temperature for twenty-two hours. The animals used in these experiments were all of the *Macacus rhesus* variety.

Of eight animals so treated, five have withstood the intracerebral inoculation of from three to six lethal doses. The serums obtained from six of these animals all contained neutralizing principles, but in varying degrees. Two of the serums completely neutralized the virus. The animals receiving these mixtures are alive and well. The remaining four serums prolonged the incubation period to twenty-five, twenty-one, twelve and eleven days, respectively. Four normal control animals showed symptoms in four and five days. A mixture of ten parts of serum and one of virus has been considered a sufficient test to determine the presence or absence of neutralizing substances. It can, therefore, be stated with considerable assurance that serums which can prolong an incubation period of five days from eleven to twenty-five days when used in the proportions of these experiments possess neutralizing substances. Lack of animals has compelled us to apply an unusually severe test. Otherwise we would have made additional tests of the serums in the proportions of ten parts of serum to one part of virus, and five parts of serum to one part of virus, and so have obtained a more definite estimate of the content of neutralizing substances.

The animals treated by this method were subjected to more than a reasonable exposure, as attested to by the effects of similar intracerebral inoculations on the normal controls. These showed symptoms of the fatal disease in four and five days. To indicate further the severity of the test to which the animals were subjected, two monkeys that presented residual paralyses, one of both lowers and the other of the right lower as a result of experimental infections with the virus of the 1916 epidemic, succumbed just as readily as the controls when injected intracerebrally with 1 c.c. and 0.5 c.c., respectively, of the same emulsion used on the treated animals.

According to experienced workers in this field, animals that have recovered from the experimental disease are considered to be highly resistant to reinfection. Yet these animals were reinfected by one-half and one-fourth the dose, respectively, that Flexner and Lewis used in their experiments. Even one minimum lethal intracerebral dose is an unusually severe test from a practical point of view, since by this method of infection the combative forces in the blood of the general circulation are circumvented. In the natural method of infection, the virus would encounter, in persons immunized by such a method as this, a surplus of immune substances in the mucous membranes, and so be neutralized before it could gain access to the central nervous system.

had entirely disappeared. At this time, the spleen had completely receded above the costal margin and could no longer be palpated.

When last seen in February, 1918, about sixteen months after the beginning of the benzene and roentgen-ray treatment, the patient still continued well, in spite of the fact that no form of treatment had been given during this period, and the number of red blood corpuscles and the percentage of hemoglobin remained within normal limits.

COMMENT

Experimental and clinical observations concerning the effect of drugs and various radioactive substances on the blood and blood-forming organs have brought forth some interesting facts regarding the relative resistance to these agents offered by the white blood cells and the red blood corpuscles. In the first instance it has been shown that the various drugs and rays employed exert a selective action on the several tissues giving origin to the formed elements of the blood; and secondly, that the leukopoietic tissues are much less resistant to their destructive action than are the tissues concerned with the formation of erythrocytes. The latter elements, it would appear, show only moderate changes in number and structure at a time when the circulating leukocytes may have almost completely disappeared from the circulation.

The observations of Heinecke and of Selling have established these facts, so far as the action of the roentgen rays or of benzene is concerned. This work shows that the roentgen rays exert a selective action on the lymphocytes, and that even prolonged irradiation will not bring about any noteworthy changes either in the number of red blood corpuscles or in the percentage of hemoglobin. Benzene, on the contrary, has a somewhat different action. This drug has been shown by Selling to act destructively first on the white cells and more especially on the nongranular elements, and later to cause a diminution in the number of erythrocytes. The experimental studies have shown, however, that in order to effect any striking anemia, the drug must be administered in large doses and over a long period of time.

It is because of this essential lymphotoxic action that the roentgen rays alone have not been found of great value in the treatment of polycythemia. Whereas benzene, on the other hand, has yielded some brilliant results in the treatment of this disease, it must be kept in mind that these good effects have usually followed the prolonged ingestion of large doses of the drug—a procedure not entirely without danger. The danger lies, first, in the severe gastro-intestinal disturbance which may follow the administration of very large doses, and secondly, in the marked destructive action which these large amounts may have on the circulating leukocytes.

It was with the hope of testing the value of smaller amounts of benzene, when combined with the roentgen rays, that the mode of treatment outlined in this paper was carried out. The patient, as will be noted from the clinical record and the table, received only 44 gm. of the drug within a period of a month, after which the benzene was stopped. The roentgen-ray treatments, however, were continued about two months longer. Although considerable reduction in the red count followed the use of benzene alone, the erythrocytes began to approach the normal level only after the seventh roentgen-ray treatment.

The good effects of the combined treatment may be attributed either to the joint action of both measures, or to the delayed and cumulative action of the benzene itself. It does not appear likely that the latter measure can be the cause, since previous observers did not succeed in reducing the red count appreciably with the amount of benzene administered to our patient. We are, therefore, inclined to attribute this successful therapeutic result to the combined action of both agents. But the manner in which the roentgen rays may have served as an adjuvant to benzene therapy in this instance is not quite clear. We would venture the suggestion, however, that the roentgen rays may act in a more destructive manner on erythropoietic tissues, which have been rendered less resistant beforehand by the toxic action of benzene.

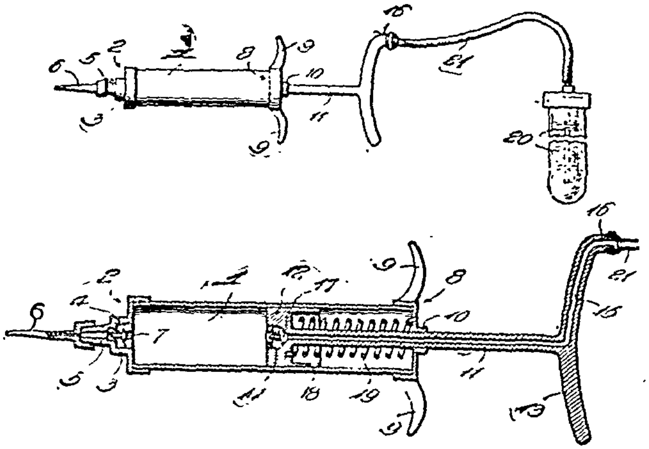
Clinical Notes, Suggestions, and New Instruments

A SELF-FILLING HYPODERMIC SYRINGE

A. N. BESSESEN, M.D., MINNEAPOLIS

Local anesthesia is growing in popularity with the medical profession. Generally we have to rely on the ordinary hypodermic syringe for the application of the anesthesia, unless one is fortunate enough to own a Farr apparatus. In the use of the ordinary syringe much time is consumed in refilling, or even in the exchange of syringes. It was with the thought of avoiding this delay that I devised the syringe illustrated.



Self-filling hypodermic syringe.

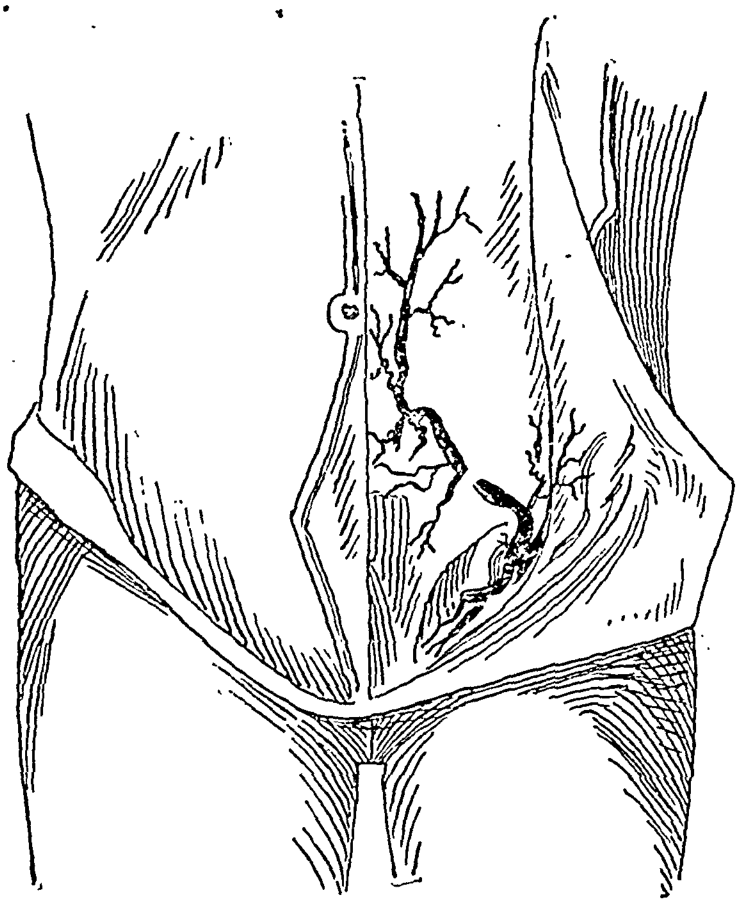
The syringe refills itself from a container attached to the syringe and suspended conveniently from the wrist of the surgeon. In this way a small or large amount of the anesthetic may be injected accurately with the least effort. In the illustration, 7 and 17 indicate the outlet and inlet valves, 11, 15 and 16 the intake channel, and 20 the container for the supply fluid.

RUPTURE OF DEEP EPIGASTRIC ARTERY BY MUSCULAR STRAIN: REPORT OF A CASE

MARK LEWIS EMERSON, M.D., OAKLAND, CALIF.

History.—A housewife, white, aged 42, with four living children, had had seven miscarriages, five of which had occurred between the third and fifth month, and two during the seventh month. She was admitted to the Merritt Hospital at 9:30 p. m., Sept. 8, 1917, and discharged as cured, November 10. The patient stated that about 5:30 p. m. on the day of admission, four hours before reaching the hospital, while trying to place a curtain rod over a window bracket, she had jumped up a few inches from the floor, extending her body on her right leg. She had suddenly been seized with a severe pain in the lower left abdomen, had fallen to the floor, and had then fainted. She had awakened to find that she had been placed on her bed. She had felt cold, with clammy sweats, and had been thirsty and very restless Her family physician, Dr. E. M. Keyes, had soon arrived and administered a hypodermic stimulant, which he had repeated before she left the house in an ambulance for the hospital. She stated that she had been in the habit of wearing a long, unusually tight corset to disguise the effect of her rapidly increasing weight on her appearance.

Examination.—Patient was somewhat pale but was not suffering from shock. She was very restless, however, and was nauseated, having recently vomited. A sensitive and painful condition of the lower abdomen would not permit a satisfactory examination. She complained of a burning sensation in the left lower quadrant. A diffuse dulness was also apparent in this region. The pelvic examination was negative, and because of the extremely restless condition of the patient, the physical examination was very unsatisfactory. The temperature was 99.6; the pulse, 100; white blood count, 15,400; polymorphonuclears, 86 per cent. The urine was normal. An enema was given, with no resulting relief from pain. One and one-half ounces of castor oil gave a free bowel movement within three hours. The following morning, the abdomen was still very sensitive. An appreciable dulness and induration were found on the left side of the lower abdomen. The patient, however, felt and looked better. The temperature was 100.6, and the pulse 90. She seemed to improve daily, with regular bowel movements and normal urine. This condition continued for eight days. The painful, indurated condition of the lower left abdomen had now become an easily palpable tumor of the abdominal wall, verified by bimanual examination.



Rupture of deep epigastric artery.

Operation.—On the ninth day I operated for what I thought might be a direct hernia of the abdomen, with the omentum protruding through the peritoneum, but below the deep fascia. I made an incision 4 inches long over the tumor in the left lower abdomen, on the outer side of the rectus muscle, extending within 2 inches of Poupart's ligament. Through the deep fascia was revealed a large blood clot, containing about two cupfuls of clotted blood. Evidently the hematoma had developed at the expense of the peritoneum, which was blood stained from the severed ends of the deep epigastric artery and vein which lay on the surface about three-fourths inch apart. The artery was easily demonstrated lying on the peritoneum. It had been severed about midway between Poupart's ligament and its entrance into the lower portion of the rectus sheath.

Although active bleeding had long since ceased, I tied both ends of the severed artery and vein, and left a few strands of twisted silkworm gut in the wound for a few days. Convalescence was uneventful, the patient leaving the hospital in three weeks. In view of her repeated miscarriages, I ordered a Wassermann test made, which was negative. November 1, I sent for the patient for further examination and verification of her history. Her blood pressure was 180 systolic. She attributes all her trouble to her long, tight-fitting corsets, which she says held her abdomen so tight that when she extended her leg, the action snapped the blood vessel.

PNEUMONIA AT A BASE HOSPITAL

RUFUS COLE, M.D.
NEW YORK
AND
W. G. MacCALLUM, M.D.
Contract Surgeons, U. S. Army
BALTIMORE

Early in February, a commission was sent by Surgeon-General Gorgas to Texas to study the pneumonia existing there. This commission was composed of Rufus Cole, W. G. MacCallum and Oswald T. Avery, Contract Surgeons, U. S. Army, Captains A. R. Dochez and R. A. Kinsella, and Lieutenants F. G. Blake, T. M. Rivers, H. John, F. A. Stevens and Wm. C. Von Glahn, Medical Reserve Corps. This special study was undertaken at the base hospital, Fort Sam Houston, San Antonio, Texas. This hospital was chosen for this work merely because pneumonia was prevailing there to a large extent at the time, and also because of its proximity to the laboratory of the Southern Department, where facilities were available for carrying out the bacteriologic and pathologic examinations. It was thought that any facts disclosed by the study there might be applicable to other camps and base hospitals. Any general application of our observations, however, must be made with reservations, for it is possible that the conditions in other hospitals may be different from those found here, and therefore that the pneumonia existing in other hospitals may differ in essential details from that present in this one.

Our preliminary survey of the cases in the hospital made it evident that not all the cases were of the same variety and that our present knowledge did not permit a ready differentiation of the cases of the different kinds. An extensive statistical study was therefore out of the question, and we decided to make a very careful clinical, bacteriologic and pathologic study of a limited number of cases.

The study was commenced, Feb. 1, 1918, and continued about six weeks. This paper is composed of extracts from the preliminary reports made by us to the Surgeon-General.

PART I. ETIOLOGY AND CLINICAL FEATURES OF THE PNEUMONIA OCCURRING IN THE HOSPITAL

TOGETHER WITH NOTES CONCERNING THE PLACE AND MODE OF INFECTION IN THE CASE OF POSTMEASLES BRONCHOPNEUMONIA[1]

By Rufus Cole, M.D.

Varieties of Pneumonia

The account of the results of our observations will be rendered more intelligible if we state briefly that we have found two distinct varieties of pneumonia in the wards of this hospital. First, there are present cases of acute lobar pneumonia, which are essentially identical with cases of this disease occurring in civil life. With all these cases pneumococci have been associated; second, there are present a large number of cases of bronchopneumonia, which differ essentially from the cases of the former disease in clinical features, pathology and etiology. The majority of these cases occur as complications or sequelae of measles, though they may undoubtedly follow other infectious diseases. The pathology of these cases is carefully described by Dr. MacCallum in his report. The etiologic agent in all the cases studied here has appeared to be a streptococcus producing lysis of red blood corpuscles when grown on a medium containing blood. Similar observations have also been made in other Army hospitals, and it seems probable that these streptococci are responsible for most of the bronchopneumonia occurring in the present epidemic of measles. Previous observations, however, suggest that other bacteria may also be responsible for cases with similar clinical and pathologic features. In the further discussion, we shall refer to these two varieties of pneumonia as "acute lobar pneumonia" and "bronchopneumonia." Finally, there occurs, in no inconsiderable number of patients, a combination of these two types of disease, or infection with both pneumococci and streptococci. In these cases, one or the other of the two varieties of disease is probably primary, secondary infection later occurring with the subsequent development of the other variety.

Since the regular hospital data were not considered sufficient for our purposes, complete histories were obtained from a series of cases of both varieties, and our own physical examinations were made and the results carefully recorded. Thirty cases of bronchopneumonia, thirty-two cases of acute lobar pneumonia, and nine cases in which the two varieties of infection were present have been studied.

It was impossible to study all of the cases of pneumonia in the hospital in this way. Consequently, in a considerable number of cases coming to necropsy, the clinical data are slight. On the other hand, many of the cases studied by us ended in recovery, and consequently the pathologic lesions present can only be inferred from the knowledge obtained in the other cases in which necropsy was performed. In twelve cases of bronchopneumonia, however, the clinical observations could be correlated with the pathologic findings.

BRONCHOPNEUMONIA

Bacteriology.—The evidence that *Streptococcus haemolyticus* is the etiologic agent in these cases is given by the study of cultures made from the blood during life and from the organs and tissues of the body after death, and by the study of the sputum coughed directly from the lung.

Cultures from the blood during life were made in fifteen cases. In only two cases was a growth obtained. In these cases a pure growth of *S. haemolyticus* occurred. The cultures were made only within twenty-four hours of death, however. Studies of the bacteria present in specimens of sputum expectorated from the lung were made in all the cases. The method employed was practically that described previously for the study of the sputum in lobar pneumonia.

Specimens of sputum directly coughed from the lung were obtained in sterile containers. After the washing of portions of this sputum, cultures were made on the surface of blood agar plates, and a small portion of sputum was injected into a mouse. After the death of the mouse, the peritoneal exudate was examined microscopically, and cultures were made from this exudate and from the heart's blood.

In all the cases that we have classified as bronchopneumonia, the cultures from the sputum on blood agar plates showed the presence of *S. haemolyticus* in large numbers. In most of the cases in which the mouse test was carried out, examination of the heart's blood showed the presence of this organism (in sixteen out of seventeen cases). In thirteen of the specimens of sputum, *Bacillus influenzae* as well as *S. haemolyticus* was found on the plates. In five instances, the patients died and came to necropsy, and in these instances *B. influenzae* was also present in the affected lung. In eight instances, *B. influenzae* was also present in the heart's blood of the mouse. Whether this organism plays any part in this disease is not known. Its very frequent presence is of much interest.

Cultures were made from the infected areas in the lungs, the heart's blood, the pleura, the pericardium, and frequently from other organs of the patients coming to necropsy. In making cultures from the lungs, the pleura over the infected area was seared with a hot knife, and a cone-shaped piece of the lung was remove with sterile instruments. Cultures and smears were then made from the tip of the portion removed. In all of the cases diagnosed as bronchopneumonia during life and all of those cases coming to necropsy which showed the presence of the lesions described by Dr. MacCallum as interstitial bronchopneumonia, *S. haemolyticus* was found to be present in the affected portion of the lung, usually in pure culture. In most of the cases in which empyema occurred, these organisms were present in the fluid in pure cultures.

It was also the rule to find these organisms in the heart's blood after death. In a few cases influenza bacilli were also present in the blood and tissues, along with *S. haemolyticus*. These cases, however, did not differ from those in which the streptococcus was present alone.

Clinical Course.—The picture of the clinical course of the disease which can be constructed from our data is necessarily incomplete and possibly incorrect in certain details. It is hoped, however, that it may be amplified and corrected by more complete studies in other camps. The study of these cases has not made it possible to differentiate, clinically, between the cases showing the lesions described by Dr. MacCallum as interstitial bronchopneumonia, and those showing the lesions described by him as lobular pneumonia. Consequently, in our discussion all these cases are termed "bronchopneumonia."

---

[1] This part of the work was carried out with the assistance of Oswald T. Avery, A. R. Dochez, R. A. Kinsella, F. G. Blake, T. M. Rivers, H. John, and F. A. Stevens.

In no uncomplicated cases have we seen wide areas f dulness with characteristic tubular breathing and other signs of consolidation. When these signs have been present, there was always a complicating lobar pneumonia. In a few cases, however, later in the disease, there has been impairment of the percusion note over a wide area, with quite distant tubular breathing over this area, but with voice sounds fairly well transmitted. The repeated insertion of a needle n these cases has failed to reveal fluid, and the needle has felt as though it were in a more or less solid lung. We have interpreted these signs as due to a quite widespread involvement of the lung, with a marked degree of proliferation and plugging of the bronchi, as described by Dr. MacCallum. These are probably the cases which go on to necrosis and abscess formation, such as was seen in three of the necropsy cases. It must be remembered, however, that in the only cases of this type that we have seen at necropsy there was a marked accumulation of fluid in the pleura.

Complications.—Focal infections, such as tonsillitis and otitis media, may be present. They have not occurred frequently in this series, however. The most important complication is empyema.

Empyema.—This condition occurs with great frequency, being present in sixteen of the thirty cases, and in all but one of the necropsy cases. In ten of the cases, the condition was diagnosed by aspiration of fluid from the chest during life. In four additional cases, fluid was obtained from the chest on aspiration, but in these cases, the fluid was only slightly turbid, and contained no bacteria demonstrable by culture.

The diagnosis of the presence of fluid or pus in the pleural cavity in these cases is frequently difficult. In the cases in which large accumulations of fluid have occurred, no great skill is required. It is probably of great importance, however, to detect the presence of small amounts of fluid, and to do this as early after the fluid appears as possible. Small amounts of fluid can be detected only by employing the methods of physical examination of the chest. Roentgen examination is of assistance in certain cases. We have already stated that occasionally, over the more intensely affected areas, there is dulness on percussion, and the breath sounds may be distant. To determine whether these signs are due to an intrapulmonary lesion or to the accumulation of fluid in the pleural cavity is frequently very difficult. The greater intensity of the dulness on percussion, when fluid is present, and the distant faint tubular breathing heard at the margin of the area, are the signs of greater importance. Fortunately, the decision can be obtained by insertion of a needle, and in doubtful cases, this may be done not only once, but many times, if necessary.

Character of the Fluid: In most of our cases, the fluid obtained has been thin, but turbid, owing to the presence of bacteria and numerous fibrinous, purulent floccules. In only three or four cases has a thick, greenish-yellow pus been encountered. The infrequency of an exudate of this character should lead one to suspect, when such fluid is found, that the condition is a complication of lobar pneumonia and not of bronchopneumonia.

Mortality.—Of the thirty patients studied by us, fourteen died and sixteen recovered, a mortality of 47 per cent. Several of the patients are still very ill, however, and will probably die. Since the cases were not taken in succession, it is impossible to say whether or not this is a fair estimate of the mortality rate. Probably the percentage of cases ending fatally in this hospital has been considerably higher than this. A most striking fact is that all the necropsy cases in our series were complicated by empyema. In many cases it has seemed that death was related directly to this complication.

Treatment.—No observations were made on the effect of any special form of treatment. Since the occurrence of empyema is an important factor in the outcome of the treatment of this complication, it deserves a few words of discussion.

Seven of the empyema patients were operated on, a rib resection with drainage being performed in each case. Of these patients, four have died. All of the others are very sick, and a fatal outcome is probable in one or more. On the other hand, of four patients in whom fluid containing streptococci was aspirated from the chest and operation was not performed, all have died. There were three cases in which fluid containing a moderate number of pus cells but no bacteria was aspirated from the chest. One of these patients was operated on; the other two were not. All three of these patients have lived, and from present indications will probably recover, though the patient operated on is still very ill. Our observations are not sufficient to enable us to draw any conclusions as to operation in this condition. They suggest, however, that in the cases in which fluid containing streptococci is aspirated from the lung, the chest should be opened and drained. But the question of operation in these cases is a difficult one, and we cannot be guided entirely by our experience with empyema complicating lobar pneumonia. The problem deserves special study.

LOBAR PNEUMONIA

During the course of our study of cases of bronchopneumonia, a considerable number of cases of typical lobar pneumonia were encountered. Some of these were chosen for study deliberately in order to have a control for the other work; in some the differential diagnosis was made only after careful investigation. One purpose of this study was to demonstrate to the hospital and laboratory personnel the fact that, under the conditions existing here, rapid and accurate diagnosis of the type of pneumococcus causing the infection in lobar pneumonia could be made. A small number of the patients were treated with serum by us or under our direction. This was also done for the purpose of demonstration.

Thirty-two cases of lobar pneumonia were studied. Only two of these patients had recently had measles: one one month, and the other six weeks previous to onset. There seemed no definite relation between the measles and pneumonia in these cases. In one other case, not included in this series, an apparent pulmonary infection with pneumococcus Type IV occurred during convalescence from measles. There was a pleural exudation of clear, sterile fluid; but the signs of lobar pneumonia were never definite.

Of these cases, seventeen were associated with Type I pneumococcus in the sputum; three with Type II; four with atypical Type II; one with Type III; six with Type IV, and one with *Streptococcus mucosus*.

The etiologic diagnosis was made within twenty-four hours in all these cases except two. In these cases, the delay was due to the fact that the sputum was very scanty and unsatisfactory, and the tests had to be repeated. The examination in both of these cases was made late in the disease. (Some of the patients were studied on admission, others only after they had been in the wards for some days.) In seventeen cases, the diagnosis was made within eight hours, the Avery medium being employed. Considering the conditions under which we worked, this result seems quite satisfactory and demonstrates the possibility of type determinations in a military hospital.

In eleven cases, the presence of fluid in the chest was determined by aspiration. In five cases the fluid was clear, or very slightly turbid. In four of these cases the fluid was sterile; in the remaining case the fluid was contaminated after renewal from the chest and cultures could not be made. In these five cases, the fluid was removed by aspiration, and all the patients recovered without operation. In five other cases, the fluid was very turbid, and cultures revealed the presence of pneumococcus Type I. All of these patients were drained. Three of them are now well or are satisfactorily convalescing. Two of them are still very ill and have irregular fever. In the remaining case the fluid was thick and green, and cultures showed the presence of pneumococcus Type II. This patient was operated on and is also convalescing.

In eight of the Type I cases, the patients were treated with serum. Two of the treated patients were found to be sensitive to horse serum, and it was necessary to desensitize them before the administration of large amounts of serum. All but one recovered promptly; this one developed empyema. This patient has done well since operation and is now convalescent. The results of this small series of cases, therefore, were satisfactory.

Of the thirty-two patients, two died; two of the empyema patients are still ill, and the result is in doubt. The others have recovered.

This experience with lobar pneumonia in this hospital leads us to believe that it does not differ essentially from that seen in civil hospitals, except, perhaps, in its relative mildness. This, however, is to be expected in a population composed of healthy young adults.

CASES OF MIXED INFECTION OR DOUBTFUL CASES

In addition to the cases which were clinically identified as bronchopneumonia and which at necropsy were found to show the lesions described as interstitial bronchopneumonia or lobular pneumonia, and the cases which were typically lobar pneumonia, both clinically and at necropsy, there occurred a series of cases which were more or less complex in their clinical, etiologic and pathologic features.

There were seven cases in which evidence was obtained of a mixed infection with pneumococcus and *S. haemolyticus,* the infections being present simultaneously or in succession. Four of these cases were in patients who had recently had measles:

The first patient had signs of bronchopneumonia beginning a few days after measles. Four days later there was an acute exacerbation of symptoms with signs resembling pneumonia. This patient developed empyema on the side of the lobar involvement; and from this fluid during life pneumococcus Type IV was obtained. Death came six days after the onset of the severe symptom. The necropsy showed the presence of lobar pneumonia of the left lower lobe and an area of typical bronchopneumonia in other portions of the lung. From the blood and the right lung, *S. haemolyticus* was isolated. From the pleural exudate both *S. haemolyticus* and pneumococcus Type IV were cultivated. That a combined infection in this case was present is certain. The chronologic course of events is more difficult to decide. It is impossible to say definitely whether the patient had a bronchopneumonia, with secondary pneumococcus infection, which led to septicemia and death, or whether the streptococcus infection occurred later, or finally whether the two infections occurred simultaneously.

The second patient had otitis media and also pulmonary symptoms lasting almost a month following measles. There then occurred an exacerbation of signs and symptoms, and the ward surgeon made a diagnosis of pneumonia. We saw him two days later and found an empyema on the left side, in addition to some signs of consolidation of the left lower lobe. The fluid from the chest contained *S. haemolyticus,* but the blood culture showed the presence of pneumococcus Type IV. The patient died two days later, and at necropsy a true lobar pneumonia was present, but no evidences of bronchopneumonia. In the cultures at necropsy, only *S. haemolyticus* was obtained from both lungs, and *S. haemolyticus* and *B. influenzae* from the blood. This case is difficult to interpret. The patient had a lobar pneumonia, and this was probably due to pneumococcus Type IV, although for some unexplained reason these organisms were not found at necropsy. Whether the streptococcus infection occcurred early in the illness or only shortly before death cannot be determined. Unfortunately, the early clinical notes are incomplete, and we have no knowledge of the severity of the early lung involvement.

The third patient developed fever and respiratory symptoms ten days after an attack of measles. In the interval, however, he had had slight, irregular fever. We saw him four days later. He had then only signs of diffuse lung involvement, with indications of empyema on the left side. The sputum contained *S. haemolyticus,* as did also the purulent fluid aspirated from the chest. No pneumococci were isolated. Four days later he was operated on, and the pleural cavity was drained. He lived almost two weeks, and then died. At necropsy an undrained pocket of pus was found between the left lung and the pericardium, and in addition there was almost complete uniform consolidation of the entire left lung. The other lung showed no evidences of bronchopneumonia. At necropsy, *S. haemolyticus* was found in all the cultures, as well as a gram-negative bacillus producing a putrefactive odor. In this case lobar pneumonia existed without the presence of pneumococci being demonstrated at any time. This may have been due, however, to the overgrowth of the culture with a putrefactive organism, which was undoubtedly a terminal invader. When the lobar pneumonia began, or whether bronchopneumonia was ever present, cannot, of course, be decided.

The fourth patient developed typical lobar pneumonia during convalescence from measles. The blood culture showed the presence of pneumococcus Type I. He developed fluid in the left chest which was purulent, and contained pneumococcus Type I and *S. haemolyticus.* He died three days after the tapping, and at necropsy no pneumonia was found, but several small abscesses in the left lung and a very large amount of purulent exudate in the left pleura. The necropsy culture showed only the presence of streptococci. No pneumococci grew.

There were three patients suffering from acute lobar pneumonia in the pneumonia wards who gave no history of measles but in whom evidence of additional infection with *S. haemolyticus* was obtained. In two of these cases the pneumococcus causing the lobar pneumonia was Type II; in one, Type I.

One of these patients, during convalescence from pneumonia due to pneumococcus Type II, developed empyema, and the pleural exudate contained *S. haemolyticus* and *B. influenzae.* He had had some cough and sore throat for three weeks before the onset of pneumonia, and it is possible that the streptococcus infection antedated the pneumonia. There is no definite evidence for this, however.

The second patient had quite a typical attack of acute lobar pneumonia, also due to pneumococcus Type II. He gave no history of any pulmonary symptoms previous to the onset of pneumonia. During convalescence, he developed an irregular fever and signs of scattered lesions in the chest. There occurred an effusion of fluid in the pleura, cultures from which were sterile. The examination of the sputum at this time, however, revealed the presence of *S. Haemolyticus,* which had previously been absent. In spite of the fact that the chest fluid was sterile, the chest was opened and drained. The signs of diffuse involvement of the lungs, however, continued, and the patient, one week after operation, is still seriously ill. The study of this case is incomplete, and the evidence of secondary streptococcus infection is not satisfactory, but is suggestive.

The third patient suffered from acute lobar pneumonia, due to pneumococcus Type I, involving the right lower lobe. Convalescence was normal for a week. Signs of pulmonary involvement persisted, however. At the end of the week, the temperature again became elevated, and the presence of fluid in the chest was suspected. Repeated insertion of a needle, however, failed to reveal fluid. The sputum, however, changed in character, and examination now showed the presence of *S. haemolyticus* and *B. influenzae.* Finally, about two weeks after the second onset of fever, a small amount of dark, foul-smelling fluid was obtained by puncture, apparently from the lung. This showed the presence of *S. haemolyticus* and the staphylococcus. About a week later the chest was opened and a lung abscess was drained. Whether the occurrence of abscess was due to secondary infection with streptococci or whether this infection was secondary to the abscess formation is, of course, not certain.

There were two additional patients seen by us in the pneumonia ward who developed empyema, with *S. haemolyticus* in the fluid. One patient had never had measles and the other had had measles two weeks previously. In the case without measles, the occurrence of pneumonia was doubtful.

This patient had been slightly ill for two weeks previous to admission, but had been performing his duties. The pleural effusion was present on admission, so infection occurred outside the hospital. The sputum contained *S. haemolyticus* and *B. influenzae,* and the pleural fluid contained *S. haemolyticus.* The patient was operated on and recovered.

In the second case, which followed measles, there were signs of lobar pneumonia with empyema. The sputum contained only *S. haemolyticus* and *B. influenzae.* The pleural exudate contained *S. haemolyticus.* The patient was operated on, and his present condition is fairly favorable. It is possible that this patient had bronchopneumonia, and not lobar pneumonia.

These cases indicate the frequency of complicated pulmonary infections in the present epidemic, and they also show the difficulty of interpreting the course of events in certain cases. It is true that in most of these cases no careful observations were made during the early stages of the illness. It seems quite certain that lobar pneumonia may sometimes occur in patients already infected with streptococci and with bronchopneumonia already present in the lungs. That bronchopneumonia occurs secondarily to lobar pneumonia is not so well shown by our cases; but they do show that in cases of lobar pneumonia, secondary infection with streptococci not infrequently occurs. This is obviously of much practical importance, suggesting that, so far as possible, patients with lobar pneumonia should be protected from infection with this streptococcus.

PLACE AND MODE OF INFECTION IN POST-MEASLES BRONCHOPNEUMONIA

From the data previously presented, there appears little doubt that a hemolytic streptococcus is the chief, if not the only, cause of the bronchopneumonia following measles which occurs among the soldiers at this post.

We have previously indicated that the infection in these cases is probably descending, occurring first in the throat, and successively involving the lower respiratory passages, and finally the lung. It therefore became of much interest and practical importance to learn whether hemolytic streptococci are present in the upper respiratory tract of all measles patients, and, if so, at what stage of the disease they are first present, or, on the other hand, whether these bacteria are present only in the throats of these patients who later develop pulmonary lesions.

We therefore first attempted to determine the prevalence of hemolytic streptococci in the throats of all the patients in the measles wards of this hospital. To do this, cultures were made from the pharynx and tonsils of these patients on blood-agar plates. The plates were incubated twenty-four hours and then studied for the presence of hemolyzing streptococci. These organisms were identified by isolation in pure culture from a single colony and by testing staining reaction, morphology, cultural characteristics, bile solubility, hemolytic activity and fermentation reactions. Hemolysis was determined by testing the power of a twenty-four hour broth culture to hemolyze an equal amount of a 5 per cent. suspension of the red blood cells of rabbits. The degree of hemolysis was recorded at the end of two hours at 37 C. Table 1 gives the results of the study.

TABLE 1.—INCIDENCE OF STREPTOCOCCUS HAEMOLYTICUS IN THROATS OF PATIENTS IN MEASLES WARDS

Total Number of Cases Examined	Number of Positive Cases	Number of Negative Cases	Per Cent. of Positive Cases
69	39	30	56.5

At the time of the examination, these patients had been in the measles wards for periods of time varying from one to fifty-five days. Of the sixty-nine patients examined, thirty-nine, or 56.5 per cent., showed the presence of *S. haemolyticus* in the throat.

These observations indicate that a large proportion of the patients confined to the measles wards harbor these organisms in the throat.

It next appeared of importance to learn whether or not this high incidence of carriers of hemolytic streptococci is peculiar to the measles wards or whether a similar state of affairs exists among the patients in other wards of the hospital. The incidence of streptococci of this variety in the throats of normal individuals under ordinary circumstances has not been determined accurately. In the presence of an epidemic of streptococcus infection, such as streptococcic sore throat, it has been found that a considerable number of healthy persons may carry this organism in the throat. On the other hand, the observers who have made fairly extensive studies on the flora of the normal throat, in the absence of epidemics of this kind, report that the occurrence of actively hemolytic streptococci in the throats is very rare. At the time of our arrival at San Antonio, it was evident that an epidemic of coryza, laryngitis and mild bronchitis existed among both the civil and military population. In some limited observations which we made, it was found that in the throats of persons suffering from this affection, hemolytic streptococci, and also influenza bacilli were occasionally present, singly or combined. It was possible, therefore, that the study of persons other than those suffering from measles might show a high incidence of hemolytic streptococci in the throats. Consequently cultures were made from the throats of patients in a ward in which the patients were suspected of having tuberculosis but who had no other disease. Table 2 presents the results of this study.

TABLE 2.—OCCURRENCE OF STREPTOCOCCUS HAEMOLYTICUS IN THE THROATS OF TUBERCULOSIS SUSPECTS (WARD 27)

Total Number of Cases Examined	Number of Positive Cases	Number of Negative Cases	Per Cent. of Positive Cases
28	6	22	21.4

The occurrence of *S. haemolyticus* in the throats of these patients is considerably less than the incidence among the measles patients. It should be mentioned that the patients in the tuberculosis ward are not rigidly isolated from patients in other parts of the hospital, transfers from this ward to another, and vice versa, not infrequently being made. Several cases of tonsillitis and pharyngitis were discovered during the process of making cultures. Moreover, these patients live in very close association, being confined in the ward and only a few of them being confined to bed.

There were two methods available to discover whether the measles patients acquired the hemolytic streptococci before admission, or whether transfer from one patient to another probably occurred in the ward. One method was to make cultures on a large number of men in the barracks from which the patients with measles came, with the object of learning whether the incidence of streptococci in the throats of these healthy men was less than that among the men in the wards; the other was to make cultures from the patients with measles on admission to the hospital and then to repeat the examinations from time to time, in order to learn whether or not any of the patients with negative cultures later acquired the organisms. The latter method was chosen as consuming less time and more likely to give definite information. The results of the study are presented in Table 3.

TABLE 3.—OCCURRENCE OF STREPTOCOCCUS HAEMOLYTICUS IN THE THROATS OF MEASLES PATIENTS ON ADMISSION, AND THE SUBSEQUENT ACQUISITION OF THE ORGANISM IN THE CASES PREVIOUSLY NEGATIVE

		Per Cent.
Total number of cases examined	44	
Number of cases positive on admission	5	11.4
Number of cases positive 3 to 5 days after admission	17	38.6
Number of cases on final examination—8 to 16 days after admission	25	56.8

An analysis of this table indicates that a relatively small percentage of patients on admission to the measles wards harbor *S. haemolyticus* in their throats. However, as the time of residence in the ward increases, the number of carriers of *S. haemolyticus* increases, until finally the percentage of incidence becomes as high as that found in the measles wards in general. Because of these observations, there seems to be very little reason to doubt that a large percentage of measles patients acquire *S. haemolyticus* in their throats for the first time during their stay in the hospital wards.

While this study is not extensive enough to be absolutely conclusive, it indicates strongly that the high incidence of bronchopneumonia during convalescence from measles is directly related to the transfer of the infectious agent from one patient to another in the wards of the hospital.

These observations led us to suspect that the frequent occurrence of streptococcus complications, especially empyema, might also be related to the possible wide distribution of hemolytic streptococci among the patients in the pneumonia wards. Although an effort has been made to admit to the wards assigned to the care of patients suffering from acute lobar pneumonia only patients suffering from this disease, it is quite certain that owing to the difficulties of diagnosis, a considerable number of patients with bronchopneumonia have been treated in these wards. We have already referred to certain of these cases.

To investigate this question, cultures were made from the throats of all the patients in two wards which contained only patients thought to have acute lobar pneumonia. Cultures were made from forty-five patients. The technic employed was exactly that used in the tests previously mentioned. It was found that twenty-six, or 57.7 per cent., of all these patients harbored hemolytic streptococci. In view of the high incidence of streptococcus infections among the lobar pneumonia patients, these results are most interesting and suggestive. There is no reason to believe that the percentage of patients carrying hemolytic streptococci on admission is larger than the percentage of measles patients who do so when admitted. This question, however, has not been investigated.

COMMENT AND CONCLUSIONS

The studies indicate that the cases of pneumonia at the base hospital, Fort Sam Houston, are chiefly of two varieties: first, acute lobar pneumonia, which does not differ essentially from that which occurs elsewhere; and second, bronchopneumonia, which in most cases, at present at least, follows measles.

The pulmonary lesions in most cases of this type of bronchopneumonia are characteristic and specific and have been studied and described by Dr. MacCallum. The etiologic agent in all the cases studied by us has been *S. haemolyticus.* There is no evidence presented by this work that indicates that pneumococcus causes the lesions and symptoms of this condition. Pneumonia following measles may be due to pneumococci, but the pulmonary lesion is then of the lobar variety. This complication of measles, however, is comparatively rare. Cases may occur in which both types of infection and both types of lesions are present. The sequence of events in such cases is difficult to determine and is probably not always the same.

Streptococcus infections following lobar pneumonia occur with considerable frequency in this hospital. Bronchopneumonia similar to that following measles may also probably occur as a sequel of acute lobar pneumonia, though the evidence for this is not conclusive. Whether in the cases of streptococcus empyema, complicating lobar pneumonia, pulmonary lesions due to the streptococci are always present or not, has not been determined.

The mortality in the cases of bronchopneumonia is very high; that of uncomplicated lobar pneumonia is low. Practically all the fatal cases of bronchopneumonia are complicated by empyema. The incidence of empyema among the uncomplicated cases of lobar pneumonia does not seem to be extremely high.

Our observations indicate that the number of measles patients harboring hemolytic streptococci on admission to the hospital is not large. The majority of the patients with measles acquire this organism during their stay in the hospital. The chance of developing postmeasles streptococcus infections is therefore increased by residence in this hospital.

A very large number of the patients suffering from acute lobar pneumonia have hemolytic streptococci in their throats. We have no direct evidence that they acquire these bacteria in the hospital, but the presumptive evidence indicates that many of them do so.

The work indicates that the high incidence of pneumonia in this hospital, and the resulting high mortality, has been due, to some extent at least, to infection occurring within the hospital itself. The conditions are not unlike those surrounding puerperal fever and surgical wound infections. While in measles, raw surfaces do not exist on which infection can occur, this disease renders the respiratory mucous membrane especially vulnerable to infection with streptococci. Possibly in other diseases, as scarlet fever and even lobar pneumonia, similar conditions exist. When infection is once started in a ward in which the patients are closely associated, the streptococci become widely distributed; they probably gain in virulence with repeated transfer through the human subject, and serious and widespread infection results.

Probably the conditions in this hospital are not unique. It is possible that the widespread incidence of fatal pneumonia in the other army hospitals may have a similar explanation.

PART II. PATHOLOGY[2]

By W. G. MacCallum, M.D.

The material for the following study was derived from thirty-seven necropsies performed on the bodies of patients who died in the base hospital of Fort Sam Houston, Texas. They were selected as cases of pneumonia, but in three of them it proved that death had resulted from other causes. Nevertheless, the lungs in these patients, as well as those from several other miscellaneous cases in which the necropsies were performed by the resident staff, were studied.

The results are by no means easy to analyze, since there are many complications, many combinations of different infections, and many variations arising from differences in the stages of the disease at which the patient died. Briefly stated, however, it appears that two main types of bacterial infection are concerned. On the one hand, there are cases due to infection with one or another form of the pneumococcus; on the other hand, many cases have occurred in which a hemolytic streptococcus is the etiologic agent. Other bacteria have been found, notably the influenza bacillus, a gram-negative bacillus of undetermined nature, and occasionally one or another of the staphylococci; but all of these appear to be rather accidental invaders, and it seems scarcely probable that they are in any way responsible for the main anatomic changes.

Analysis of the cases appears to show fairly conclusively that the pneumococcus is responsible for those in which lobar pneumonia was found. The *Streptococcus haemolyticus,* in most instances, seems to cause a peculiar form of bronchopneumonia, which on account of its anatomic characters I have designated "interstitial bronchopneumonia." There are, however, some cases in which this organism, growing in overwhelming numbers or with especial virulence, produces a patchy pneumonia of a type more closely resembling the familiar lobular or bronchopneumonia found so often as a terminal event in persons dying of some chronic disease, or in those in whom aspiration of infected material has occurred. This may be referred to as "lobular pneumonia."

One of these infections may be superimposed on the other, and there may even be found lesions corresponding to each in the same lung.

Fibrinopurulent pleurisy with abundant exudate has occurred with extreme frequency in these cases.

Since it is recognized that pneumonia frequently follows measles, this relation was especially studied. There were fifteen definite cases of measles in the series, and in eleven of these the interstitial bronchopneumonia was found. Two showed, at necropsy, lobar pneumonia alone, two lobular pneumonia alone, while two presented a combination of lobar and interstitial bronchopneumonia. In all there were seventeen cases of interstitial bronchopneumonia, and in the six cases of this condition not definitely following measles, no history of measles was obtained in five, although it was conceded that in the course of the great local epidemic these men might have passed through mild attacks of measles which were not mentioned when the clinical history was taken. The sixth case was at first regarded as measles, but later as scarlet fever. From all the cases of interstitial bronchopneumonia the hemolytic streptococcus was isolated, and it seems clear that this is the true causative factor, whether it gains entrance on the basis of a predisposing measles or otherwise. Details concerning all these relations will be given in full in a later report, but in this preliminary report it is necessary to describe the following conditions as they occurred in this series: (1) interstitial bronchopneumonia; (2) lobular pneumonia; (3) lobar pneumonia; (4) empyema; (5) combined infections; (6) other complications.

1. INTERSTITIAL BRONCHOPNEUMONIA

This is the condition already fairly well known through the work of Bartels, Delafield, Steinhaus, Hecht and others as occurring in children as a sequel of measles, whooping cough, etc. Their descriptions correspond closely with what we have found in adults, except in the general lack of complicating empyema in children, and in certain minor histologic details, notably the presence in the lungs of children of extraordinary giant cells derived from the epithelium. None of these writers determined the nature of the bacteria concerned. On the other hand, although it has been recognized by various workers in this country that the hemolytic streptococcus is to be found in the bronchopneumonia following measles, none of them seems to have determined the exact nature of this peculiar bronchopneumonia. The association of the hemolytic streptococcus with the interstitial bronchopneumonia must, therefore, be especially emphasized.

The term "interstitial bronchopneumonia" was chosen as expressing briefly the salient features of the lesion. It may not be the most satisfactory term possible, because it fails to describe accurately the earliest stages, and leaves out of account the process of organization of the exudate which is very common; but any term that could describe the whole course of a progressive process would be unwieldy.

The interstitial bronchopneumonia has been studied in various stages in different cases and found to produce extraordinarily different appearances as it progresses.

In the earliest stage, the pleural surface of the lung is smooth and glistening. The lung is, in general, air containing, although atelectatic patches may be making their appearance. On section, small hemorrhagic foci are found scattered through the lung, each showing, as a rule, a gray rather opaque center. These foci measure from 2 to 3 mm. in diameter, sometimes more, and are so small that several may occur in one of the secondary lobules of the lung, that is, in one of the lobules marked off by the interlobular septa (W. S. Miller). Microscopically, it is found that these foci represent the ends of the bronchioles together with the adjacent alveoli. The bronchiole and the ductulus alveolaris are filled with leukocytes, among which streptococci are found in pairs or in short chains. There is some infiltration of the bronchial wall with leukocytes, and the adjacent alveoli contain a few leukocytes, occasional streptococci, coagulable fluid, and great numbers of red blood corpuscles. Not only the alveoli which form a continuation of the bronchiole, but also those which lie near its wall, seem to be affected.

---

[2] This part of the work was carried out with the assistance of Lieut. W. C. Von Glahn, M. R. C., U. S. Army.

In a somewhat later stage the lung can still be distended with air, although the patches of collapse are more extensive. On section it is found to be studded throughout large areas with small, gray nodules which project above the cut surface like miliary tubercles, and are often surrounded by a red or grayish halo. At this time there may be visible a minute cavity or depression in the center of each which marks the lumen of the bronchiole. This may be represented, however, by the opaque contents of the bronchiole. These nodules have been mistaken by more than one for miliary tubercles, and it seems conceivable that the peculiar appearance of this and later stages may be in part, at least, responsible for the almost universal statement that measles is commonly followed by tuberculosis. Microscopically, such nodules are found to consist of a bronchiole filled with exudate of leukocytes, sometimes, but not often, associated with fibrin. The epithelial cell layer lining the bronchus is partly disintegrated or detached. The bronchial wall is hyperemic and thickened largely by the infiltration into its crevices of numbers of mononuclear wandering cells which have replaced the leukocytes. The alveoli about the bronchiole appear to contain less blood at this stage; only those immediately continuous with the ductulus alveolaris contain polymorphonuclear leukocytes; the others about the bronchiole usually contain a network of fibrin with mononuclear cells. The alveolar walls in the immediate neighborhood of the bronchiole are thickened by an infiltration of mononuclear cells (lymphocytes, plasma cells and larger wandering cells). Surprisingly few streptococci are found, and those chiefly in the bronchial exudate. Fibrinopurulent pleurisy, often with excessive effusion of greenish, turbid fluid, accompanies the process from this stage on.

In a still later stage the lung is usually much collapsed, dark blue, flabby, and airless except in the anterior portions. This is produced chiefly by the pressure of the pleural exudate, but partly by the occlusion of the bronchioles. At this stage, shotlike nodules 3 or 4 mm. in diameter may be felt all through the lung. On section, the pasty, airless lung sinks into a concave surface, leaving the gray peribronchial nodules projecting conspicuously. The interlobular septa have by this time become greatly thickened and infiltrated with cells and fibrin so that they stand out most conspicuously as whitish-yellow lines, marking out the whole lobulation of the lung in polygonal fields. In each of these fields there may be three or four projecting nodules which now usually show distinctly a central bronchial lumen. The surrounding tissue may be fairly dense, so that the peribronchial thickening is marked out chiefly by its opaque whiteness. Hemorrhage may in some cases stain the outlying regions about the nodules. If the bronchi be opened with the scissors, they are found to be slightly dilated toward the periphery of the lung, where they become thick walled as they run into the terminal portion which forms the center of the nodule. The contents are thick and glutinous. Microscopically, such a lung shows a very great infiltration of the bronchial wall with masses of mononuclear cells. The epithelium usually still persists in places, although much of it is desquamated. The lumen is filled with exudate of leukocytes with rather few chains of streptococci. Sometimes all the lining of the bronchus has disappeared so that in cross section it appears like an abscess. The walls of the adjacent alveoli are greatly widened and stuffed with mononuclear cells, desquamated epithelium, fluid and rather dense plugs of fibrin. Further out the alveolar walls are still thickened and infiltrated, and the alveoli contain chiefly fluid and desquamated epithelium. At this stage, organization of the exudate in the bronchi and the alveoli is usual. Indeed, this organization occurs with surprising rapidity, so that it may be quite advanced in patients who have apparently been ill only about ten days or two weeks. In the bronchi the new connective tissue and blood vessels arising from several points in the wall pervade the exudate and form richly vascular columns of fibrous tissue which extend into the alveoli and branch into each one. The lymphatics in the walls of the bronchi and blood vessels and in the interlobular septa are distended with mononuclear cells and fibrin, and contain numerous bacteria. The bacteria apparently reach the pleural network in this way, and this seems to be the most plausible explanation of the infection of the pleura. The interlobular septa and perivascular tissues are densely infiltrated with wandering cells and become very conspicuous. The pleural surface is covered with a thick, shaggy layer of fibrin, and the pleura itself is greatly thickened by being converted into a vascular granulation tissue which is gradually replacing the fibrin.

Streptococci are present in great numbers on the surface of the fibrinous exudate, as well as in the purulent fluid in the cavity of the pleura. It is to be noted that they, unlike the pneumococcus, are not to be found scattered everywhere in the meshes of the fibrin. It seems possible that they may digest and destroy the fibrin, but at any rate they are found only on its free surface. They are not engulfed by phagocytes as freely as are the pneumococci, and they are found less frequently in the tissues themselves. Even when in an inflamed tissue, such as the lobulated, fat masses which project into the pleura from the outside of the pericardial sac, streptococci are found in a matted layer over the free surface, they can be traced down into the crevices between the lobes of fat only so far as these are freely open. If the surfaces adhere no bacteria are found in the obliterated depth of the crevice.

In still later stages, more extensive infiltration of the peribronchial tissue occurs, and solid yellowish patches from 1 to 2 cm. in diameter appear. The induration about these, with edema and hemorrhage, becomes confluent, so that quite large areas may appear consolidated. As to the nature of the healing process and recovery from this change, we have had no opportunity to learn anything.

In one case in which in some parts of the lung the lesions just described occurred in a moderate stage of advancement, other areas showed a great increase in the number of streptococci, with a wide dissemination into the tissue and a correspondingly intense inflammatory reaction. In other cases, much later, after a long course in which empyema of long standing has been drained by operation, the lung has been found to contain extensive abscesses, sometimes confluent into large, purulent areas. In such cases, and in these alone, one may expect to find secondary lesions in distant organs. It is rather remarkable that this particular hemolytic streptococcus seems to be an organism of rather slight virulence, with no tendency to spread through the body. Septicemia occurs only in the hours just before death, if at all, and in only one protracted case was there found an infarct-like lesion in the spleen. In all the others, the abdominal organs were normal.

2. LOBULAR PNEUMONIA

In these cases there was evidently an overwhelming infection with a virulent organism, or what amounts to the same thing; the patient offered no resistance to the invasion. The lungs present irregular, patchy, hemorrhagic areas of consolidation which are not especially peribronchial or limited in size. In them the streptococci are found in amazing numbers, often in long, tangled chains, scattered through the alveolar contents as well as in the exudate in the bronchi. In this respect the condition contrasts with that found in the interstitial bronchopneumonia. The exudate itself is chiefly composed of polymorphonuclear leukocytes, with some blood. There is nothing especially characteristic about this process, but it does occur after measles and is sometimes associated with the formation of areas of necrosis of the whole tissue which subsequently assume the appearance of abscesses. These are really not typical abscesses, but rather necrotic areas of consolidated lung tissue loaded with great numbers of bacteria. There were four of these cases.

3. LOBAR PNEUMONIA

Thirteen cases of lobar pneumonia occurred in this series and presented the well known anatomic picture which need not be described. In ten of them the pneumococcus was found, but in the remaining three it was missed, apparently because it was overgrown by the hemolytic streptococcus or by other organisms, since all of these were protracted cases with empyema, in which death occurred some days after operation and drainage of the open pleural cavity.

In four cases, pneumococcus Type IV was isolated. Two showed the presence of Type I and two Type II. In two the type remained undetermined.

It seems very probable that in all the cases the lobar form of pneumonia was caused by the pneumococcus. In those in which the pneumococcus was not obtained in culture, organisms morphologically like them and having the characteristic distribution of the pneumococcus are seen in the sections of the affected lung.

Secondary infection with the hemolytic streptococcus seems to have occurred in some cases, although it remains difficult to tell whether the streptococcus may not have preceded the pneumococcus. In two cases in which the pneumococcus seemed to predominate at necropsy, it was thought probable that the streptococcus infection had been followed by that with the pneumococcus. On the other hand, four or five cases showed the streptococcus in great numbers at necropsy, while the pneumococcus was found only in such lesions as a vegetation on the heart valve or an abscess in the rectus muscle. In one case the pneumococcus was found only in the pleural fluid. In another it had been present in the blood before death. In such cases it seemed probable that the pneumococcus had been outgrown and replaced by the streptococcus.

Of the thirteen cases, five showed the pneumococcus alone. In none of these was there any empyema or excessive outpouring of fluid pleural exudate. But of the remaining eight cases in which there was also a streptococcus infection, there was empyema in all except one, in which both pleural cavities were obliterated by old adhesions.

Certain histologic features with regard to the distribution of pneumococci may be mentioned. While in the case of the interstitial bronchopneumonia the streptococci are in most cases present in relatively small numbers and then confined chiefly to the exudate in the lumen of the bronchus and the immediately adjacent alveoli, to the contents of the lymphatic and the surface of the pleural exudate, the pneumococci in lobar pneumonia are present in great numbers and are scattered diffusely through the whole lung and everywhere through the pleural exudate. It is true that there are some cases of intense infection in which the streptococci grow in immense numbers throughout the affected portions of the lung; but ordinarily they are not to be found, or only rarely seen in the fibrinous exudate of the outlying alveoli. In the lobar pneumonia the pneumococci are rather more abundant in the bronchioles and ductuli alveolares than in the more peripheral alveoli; but many are to be found intimately mingled with the network of fibrin in all the alveoli and in the pleural exudate. The activity of phagocytes appears to be far greater in the case of the pneumococcus, so that great numbers of them are found enclosed in the leukocytes, while most of the streptococci appear to lie free in the exudate.

The transportation of the organisms by way of the lymphatic channels, in the walls of the blood vessels, and interlobular septa and pleura is striking in the case of the pneumococci, as well as of the streptococci. It seems probable, although not proved, that it is in this way that the pleura becomes infected. Injections of the lymphatics from the pleural network gave beautiful preparations showing the connections of this network with the enormous, deep lymphatics which run toward the hilum of the lung, in the walls of the bronchi and blood vessels, and in the septa. These aided in the recognition of the relation of the bacteria to the lymph channels.

4. EMPYEMA

Empyema occurred in twenty-six of the thirty-seven cases of the series. In every case in which there was empyema, *S. haemolyticus* was demonstrated, and although empyema occurs in pure pneumococcus infections, only those cases in this series in which there was also a streptococcus infection developed actual empyema. The exudate appears quite early in the cases of interstitial bronchopneumonia, and is usually a thin, turbid, greenish fluid with floating shreds of fibrin and a relatively thin, fibrinous covering over the lung. Usually this fibrinous exudate cannot be readily peeled off, but is intimately adherent to the lung and partly organized. Very large amounts of fluid may accumulate — in one instance several liters. The effect is, of course, largely mechanical, causing the collapse of the lung, with corresponding cessation of its function; but it seems that the presence of such a huge culture of streptococci, which appear to grow in enormous numbers in a position in which they are removed from actual contact with the tissues, must be a serious menace to the patient. Further studies should be made with regard to the toxic properties of this fluid and to the presence of bactericidal substances there.

After operation, the pleural cavity tends to become infected with various organisms which confer an extremely foul odor on the exudate. Encapsulated pockets of purulent fluid are often found between the lobes, even though the main cavity may have been fairly well emptied.

5. COMBINED INFECTIONS

Mention has already been made of the fact that both the pneumococcus and the streptococcus may occur in the same individual, and clinical study may show definitely which of these infections appeared first and which was superimposed. It is difficult to arrive at any conclusion as to this from the anatomic conditions, for the ordinary criteria of the duration of an inflammatory process—organization of exudate, production of mononuclear infiltration and indurative new growth of tissue in the framework of the lung — appear so rapidly in the interstitial bronchopneumonia and are so delayed in lobar pneumonia that they help but little.

In three cases there has been found in the lungs a definite intermixture of the anatomic lesions of lobar pneumonia with those of interstitial bronchopneumonia. These conditions seem to tend to exclude each other to some degree, even when they occur side by side in the same lung; but in some places the characteristic lesions of interstitial bronchopneumonia are found embedded in the uniform consolidation of a lobar pneumonia, emerging clearly into view as one leaves the area of lobar consolidation and passes over into the rest of the lung. In two cases the pneumococcus was recovered from the area of lobar consolidation, the streptococcus from the uncomplicated foci of interstitial bronchopneumonia in the same lung. These organisms are, however, too much alike, morphologically, to allow one to recognize them with certainty, in stained sections, in association with their specific lesions, when they occur together.

6. OTHER COMPLICATIONS

Complications with regard to other organs are rare in the cases of infection with this hemolytic streptococcus. Pericarditis occurred a few times, but most of the cases of pericarditis were associated with pneumococcus infection.. Otitis media is recorded in several cases. There were two cases of acute nephritis, probably not dependent on this infection, since the kidneys in all other cases were normal. On the whole, there seems to be a very striking absence of involvement of any organs other than the lungs.

The range of complications in the case of pneumococcus infection has been rather greater. There were four cases of pericarditis, one of peritonitis, one of symmetrical bilateral abscess of the rectus abdominis muscles, and one in which death occurred suddenly in convalescence, from embolic occlusion of the pulmonary arteries.

SUMMARY

In the Army camps represented in this hospital, measles has been prevalent. Pneumonia occurred frequently, but not always as a sequel to measles. The nature of measles is unknown, and we have had no opportunity to learn what anatomic changes measles alone can produce. But it does produce coryza, conjunctivitis and laryngitis, and these conditions appear to predispose to infection of the respiratory tract with bacteria. This predisposition is made evident by the great proportion of the cases of the series in which streptococcus infection followed measles; but it is evident that streptococcus infection may occur in a person who has not had measles, and it is quite probable that other diseases, such as scarlet fever, predispose to its entrance in the same way as measles. When *S. haemolyticus* gained a foothold, it usually caused in this series of cases the anatomic complex called here interstitial bronchopneumonia." This is the same whether it is preceded by measles or scarlet fever, or by no other disease, and its characters are due to the specific effects of the streptococcus. When lobar pneumonia followed measles, the pneumococcus was in this series accompanied by the streptococcus, and in some cases the lobar pneumonia was complicated, anatomically, by the corresponding bronchopneumonia.

Infection with the hemolytic streptococcus does not always cause an interstitial bronchopneumonia, but may produce a patchy lobular pneumonia.

One of the most interesting features of our study of the cases in this hospital is the recognition of the invariable connection of *S. haemolyticus* with that characteristic anatomic lesion which was well known, but to which we have for convenience given the name "interstitial bronchopneumonia." This lesion is easily recognized in all its stages by its gross appearance, since the prominent, gray, solid peribronchial nodules with surrounding edema, hemorrhage, organization and induration bear no resemblance to areas of pneumonic consolidation, which are homogeneous, solid patches, on the cut surface of which a plug of exudate projects from each alveolus. The microscopic appearance, as described above, is equally specific and characteristic, and there is no possibility of confusion with lobar or lobular pneumonia.

Empyema is a practically constant accompaniment of this condition, and is of extremely serious import.

The organism does not seem to be very virulent, and there is little tendency for it to enter the blood stream or to produce complicating lesions in distant organs.

Lobar pneumonia due to the pneumococcus has been found in many cases, not especially related to the occurrence of measles, but often complicated by secondary or coincident infection with *S. haemolyticus*. Its characters are exactly as seen elsewhere.

A Backward Community.—"We have no hospital, no visiting nurse, no dispensary and our supervisors make no provision for tuberculous persons. In things of this kind our county is like the dog's tail—always behind. It seems nothing will get them out of this rut. We have a board of health here and the chairman does not report his own cases, or quarantine, and the restrictions are very poor. Officially we know of but one case of tuberculosis and that was found by the examiners of the exemption board."—Report in Illinois *Health News*, August, 1917.

A METHOD OF FACILITATING THE SERUM DIAGNOSIS OF SYPHILIS UNDER WAR CONDITIONS *

HIDEYO NOGUCHI, M.D.
NEW YORK

The necessity for fresh guinea-pig serum and fresh sheep corpuscles in the original Wassermann technic renders that test impracticable unless these two factors are obtainable in the laboratory. I have already introduced a procedure in which the test is made possible without the use of fresh sheep corpuscles, and this antihuman hemolytic method has found wide adoption, notably in the laboratories of the United States Army and Navy. This test, however, still requires the use of fresh guinea-pig serum as complement. Considerable apprehension is being felt at present with regard to the availability of guinea-pigs and sheep to supply the necessary material for carrying out the serodiagnostic test for syphilis according to the methods hitherto in use, and a method which renders the test independent of these resources should be welcome at this time, when economy of labor, expense and time is particularly urgent. That such a method is possible, without sacrifice of the reliability of the test, is to be shown in this paper.

THE VARIOUS ELEMENTS REQUIRED TO COMPLETE THE TEST BY THE NEW METHOD

As is well known, five different elements are concerned in any complement fixation test, to which class the Wassermann reaction belongs: complement, amboceptor and corpuscles, constituting the hemolytic system; antigen and antibody. The hemolytic system merely serves to indicate, by the occurrence or nonoccurrence of hemolysis, the presence of a specific reaction in the mixture of patient's serum and antigen. In other words, when an antibody is mixed with the specific antigen, it produces a compound which fixes or deviates complement and prevents the latter from taking part in hemolysis; consequently hemolysis cannot occur in such a mixture.

In the ordinary Wassermann test the antisheep system is used, fresh guinea-pig serum being employed as complement, together with antisheep amboceptor (rabbit) and sheep corpuscles. The patient's serum is used as the source of syphilitic antibody, but only after removal of the native human complement, present in every fresh serum, by heating the serum to 55 C. for thirty minutes (inactivation). The serum contains varying amounts of both the complement and natural antisheep amboceptor, which, if left unmodified, will constitute uncertain factors in the test. The native complement is therefore replaced by guinea-pig complement, which can be accurately titrated and added in uniform quantities. Fresh human serum also contains very often enough natural hemolysin for sheep corpuscles to cause serious disturbance in the result. While inactivation removes the complement it leaves the natural antisheep amboceptor intact, and when the latter exists in excess the degree of hemolysis produced is accelerated in spite of the use of a definite amount of guinea-pig complement and immune antisheep amboceptor. On account of the disturbing influence of this unknown and often excessive amount of natural antisheep amboceptor, in certain laboratories the serum is being treated with sheep corpuscles in order to remove them by absorption, a very tedious and time-consuming procedure if necessary in the case of 100 or more specimens of serum. Absorption involves the mixing of the inactivated patient's serum with washed sheep corpuscles, subsequent incubation at 37 C. for one hour, and finally separation of the serum from the corpuscles by centrifugation, and with all these preliminary preparations of the patient's serum the final results are no more reliable than those obtained by the antihuman hemolytic system in which there is no disturbing complement or amboceptor from natural sources, and the amounts of complement and amboceptor are always definite and controllable, antihuman amboceptor (immune rabbit) being used in combination with guinea-pig complement against human corpuscles.

In the present method the native complement present in fresh human serums is used as complement in a hemolytic system which comprises, besides the human complement in this form, antihuman amboceptor and human corpuscles. The patient's serum serves as the source of syphilitic antibody as in any other method. The only difference between my antihuman heterohemolytic system and the new hemohemolytic system is that the latter uses human complement instead of guinea-pig complement.

As already stated, the complement content of fresh human serum is variable to some extent, but the majority of specimens contain a quantity which may be taken as a standard for test. Out of 429 fresh specimens (not more than 72 hours old), twenty-two were found to contain an amount of complement less than the average, a few of these containing no complement at all. If the deficiency is slight, it may be remedied by the use of an additional amount of amboceptor; if greater, these serums must be tested with the addition of fresh negative serum as complement. As the complement gradually disappears from the serum on standing, it should be examined in as fresh a state as practicable. Even if kept in a refrigerator after withdrawal from the patient, it should not be older than 48 hours when tested. The method is equally applicable, however, to those serums which have become inactive on standing or have been artificially inactivated by heating to 55 C. for thirty minutes, or to cerebrospinal fluids; in these instances it is only necessary to add an adequate quantity of fresh human serum known to contain sufficient complement and to be free from syphilitic fixing principle.

TECHNIC

Following is a brief description of the technic of the new test, for more extensive details of which the reader is referred to the article appearing in the *Journal of Experimental Medicine:*

> The patient's serum, not older than 48 hours (at refrigerator temperature), is used in a dose of 0.1 c.c. for each of two tubes. One tube then receives 0.1 c.c. of antigen and 0.9 per cent. saline solution; the other (control) receives saline solution only. The total volume for each tube is made 1.3 c.c.
>
> The antigen consists of a 1:10 saline emulsion of the acetone insoluble fraction of tissue lipoids dissolved in pure methyl alcohol in a ratio of 3 per cent. (for standardization, etc., the reader is referred to my work in connection with the antihuman system[1]).

---

* From the Laboratories of the Rockefeller Institute for Medical Research.

[1] Noguchi, Hideyo: Serum Diagnosis of Syphilis, Ed. 3, Philadelphia, J. B. Lippincott Company, 1912, p. 79.

After an incubation of half an hour in the water bath at 37 C., the tubes are removed from the incubator and to each are added 0.1 c.c. of a 10 per cent. suspension of washed human corpuscles, and 0.1 c.c. of a dilution of the antihuman amboceptor representing one hemolytic unit. The contents of the tubes are well mixed and the tubes returned to the incubator for a second incubation of the same duration, during which two or three shakings are necessary in order to insure a uniform reaction of the reagents. After completion of the second incubation, the tubes are left at room temperature for about half an hour before the results are read. In case hemolysis is incomplete in the control tubes at the end of the thirty minute incubation period, the addition of another unit of the amboceptor to both tubes and another period of incubation are indicated. If hemolysis is still incomplete, the specimen should be tested anew with the addition of 0.1 c.c. of fresh active negative human serum (as complement).

When inactivated serum is tested, the amount used for each tube is 0.2 c.c. In the case of old serum not artificially inactivated, the amount is 0.1 c.c. In the case of cerebrospinal fluid, 0.5 c.c. of these specimens are devoid of complement and require the addition of 0.1 c.c. of human complement (negative serum). The subsequent procedure is the same as that described for the examination of fresh serums.

Controls, consisting of a known positive and a known negative serum, should of course be provided for each test, as in any other method.

PRACTICAL RESULTS

The test has been applied to several hundred specimens of human serums and a number of cerebrospinal fluids, with altogether satisfactory and consistent results, entirely in accord with those obtained with my antihuman heterohemolytic system (guinea-pig complement, antihuman hemolytic amboceptor, and human blood corpuscles), as well as with those obtained by Wassermann's antisheep hemolytic system.

Too much emphasis cannot be placed on the importance of using an antihuman hemolytic amboceptor which is highly potent, and human serum which is as fresh as possible. A suitable antihuman hemolytic serum should be able to produce hemolysis of 1 c.c. of 1 per cent. human corpuscle suspension in a dose of 0.01 c.c. or less in the presence of 0.1 c.c. of fresh human serum (complement) within from twenty to thirty minutes at 37 C. in a water bath. An amboceptor serum weaker than this gives a less satisfactory result. It is estimated that ten immunized rabbits will yield material (antihuman amboceptor) sufficient to test about 20,000 specimens within a period of one month.

A detailed and extended report of this method, which seems to be especially adapted to use among armies in time of war, will be found in a forthcoming issue of the *Journal of Experimental Medicine*.

Chestnuts and Acorns as Sources of Carbohydrate.—According to the *Lancet*, following some one's suggestion horse chestnuts have been collected and utilized as a source of carbohydrate in the manufacture of munitions in England, and later, on the suggestion of the *Lancet*, acorns have been subjected to analysis with the same idea in view and have been found to contain a greater proportion of carbohydrate than horse chestnuts. In an article read by Julian Baker and R. F. E. Hilton before the Society of Public Analysts and Analytical Chemists they set forth the results of analyses of these two seeds. In the chestnut it was found that the total amount of starch varied from 21.9 to 47.8 per cent., and the total sugars from 11.7 to 19.1 per cent.; in the acorn the starch was said to vary from 55.7 to 57.1 and the total sugars from 6.8 to 8.98. Acorns or chestnuts with their full moisture content yielded, after hydrolysis with acid, 11.5 to 12.7 per cent. of alcohol, or 32 to 36 gallons of alcohol per ton of nuts.

Therapeutics

BOILS AND CARBUNCLES

These frequent and unwelcome visitors are always due to an infection. The greatest preventive is constant cleanliness of the back of the neck, the axillae, and the gluteal, perineal and genital regions, which are the parts most frequently affected with boils. The back of the neck is the most frequent place, in men, for boils and carbuncles to occur. Infection readily occurs in the hair of the lower part of the occiput and upper neck region. Pustulations and boils in this region are due to too infrequent hair cutting and shampooing.

A boil having occurred, contiguous hair follicles may become infected, or more distant parts of the body may develop one or more boils. Doubtless such isolated boils are frequently caused by direct transmission by scratching with contaminated fingers. Frequently boils occur from infection transmitted by way of the blood or lymphatics from some focus of suppuration; or a boil may infect the blood and cause crops of boils and repeated attacks after periods of remission. Repeated crops of boils may occur from foci of infection in the nose, nasal sinuses, tonsils, teeth and gums; they are not as likely to occur from a suppurating ear, from a fistula, or walled-off sinus, but it cannot be too frequently reiterated that foci of infection in the nose and mouth are a menace. Diabetes particularly predisposes to boils.

ETIOLOGY

A furuncle, or boil, is an inflammation of the deeper layers of the skin and adjacent subcutaneous tissue, generally circumscribed about a hair follicle or sebaceous gland. The *Staphylococcus pyogenes-aureus* seems to be the most frequent germ of infection. The intruder, of course, rapidly propagates his species, irritation takes place, the blood vessels of the region become dilated, leukocytes hasten to the defense of the patient, and tumefaction, heat, and pain develop. The afflicted area becomes distinctly circumscribed, and, if not maltreated, may keep the infection within the bounds of the circumscription, with—if many lymphatics are in the region—a rather rapid congestion of the adjacent glands. These also become secondary defenses against infection of the body. The pressure of the part increases, circulation in its center is interfered with, and the central part or core of the inflamed region becomes necrosed, soon softens, and breaks through the skin, and more or less thin pus, with blood, escapes. This generally occurs in about a week. Soon after this the central dead tissue becomes loosened from the healthy surrounding tissue and is easily removed or evacuated. The cavity then granulates and rapidly heals.

TREATMENT

If a boil is first seen when it is only a slight nodule with a punctate white speck on the skin, it has long been considered that abortive treatment is advisable, and that most recommended has been to puncture through this white or red point on the skin into the hard tissue with a toothpick or wooden applicator, which has been dipped in liquid phenol (carbolic acid). Or, with a hypodermic needle, a drop or two of phenol has been injected directly into the center of the hardened part. However, although many times successful, the majority of boils cannot be so aborted, possibly because they are rarely seen at this early stage.

When a boil is first seen well on its way, incision before liquefaction and suppuration should be considered, although sometimes it does not hasten the process and may increase the pain.

The surrounding tissue of a boil should always be kept [illegible] with some mild antiseptic wash, as one of the liquid soaps, or even cleansed with a little ether. Then a wet dressing may be applied, best with some alkaline wash. Gauze saturated with such a solution and placed over the part, and a piece of oil silk over it, should be gently strapped or bandaged on. The gauze should be kept constantly moist with warm water. If the skin tends to become red and irritated about the boil, it should be soothed with petrolatum or with a dilute glycerin. No strong antiseptics should be used, any more than momentarily, on the skin. Mercuric bichlorid dressings, so long used and so much overused, are bad treatment for the skin in these cases.

If the part around the boil is hairy, it should be gently and carefully shaved or closely clipped, and when the skin is perfectly dry, iodin may be painted once around the part; then proper simple cleanliness will prevent later infection of the hair follicles.

As soon as the boil is opened, or it has come so near the skin that it is best to incise the outer layer of skin to evacuate the pus, it should be dressed frequently. Besides the cleansing of the skin about the part with alkaline washes, an ointment, as sterile petrolatum, may be spread around on the healthy skin to prevent the more or less irritant excretions from the boil causing irritation to healthy parts. The wet alkaline poultices should be continued as long as there is a hard, inflammatory area. As soon as this induration has greatly diminished, the poultice part of the wet dressing should be stopped, that is, the oil silk, rubber tissue, or waxed paper should be omitted from the dressing, and simply the moist gauze placed over the boil. This wet dressing should be frequently changed, so that no pus is dammed back into the boil and free exit is constantly possible. This means that the dressing should be done at least twice in twenty-four hours, and better, three times.

At each dressing, little pieces of dried pus or tissue should be gently removed with forceps, and just enough pressure brought to bear to bring the particles of dead tissue within reach of the forceps; no squeezing should be allowed.

CARBUNCLES

It is practically impossible to determine in most instances that a patient has a carbuncle. An apparent boil is likely to develop into several boils, with several openings, and becomes a carbuncle. Carbuncles are more likely to occur in men, and in older men than in young men, and more frequently on the back of the neck than on any other part of the body. However, wherever a carbuncle is located, on account of the large amount of tissue involved, there is always more or less danger from a phlebitis with thrombosis and possible direct infection of some large blood vessel.

It is necessary that such a multiple infection as a carbuncle should have free opening for evacuation as soon as suppuration occurs. It may be even advisable for a surgical decision as to whether or not radical excision is advisable to prevent the constant danger of infection in one of the large veins of the head. Carbuncles on the upper lip or near the nose are very dangerous.

It should be remembered that it is always possible for a boil or carbuncle to produce septicemia, and even a serious septic process of deeper structures of the body or of bones. In other words, while the individual boil is being treated, every possible focus of infection must be sought, and if one is found, means taken to eradicate it. A history of repeated boils and pustulations indicates a focus somewhere, and if it is not in direct evidence, all crowned and bridged teeth are under suspicion until the roentgen ray has proved them innocent.

GENERAL TREATMENT

As to general treatment, anything that makes for appetite, good digestion, proper movement of the bowels, and nutrition works for a successful fight against furunculosis. One of the recommended treatments is yeast. The ordinary compressed yeast cake is easily obtained and administered. The proper dose is about one third of a yeast cake, dissolved in a glass of water, twice a day. This makes a sour drink, and is not disagreeable to most persons. If it causes the bowels to become loose, the amount should be diminished. Yeast may have a beneficial action in gastro-intestinal sluggishness, and apparently has power to change the flora of the intestine.

Sulphuric acid and nitrohydrochloric acid have been recommended in furunculosis, and sulphur is also an old-fashioned treatment. If the patient is anemic, iron in some form should be given.

When there are multiple small spots of infection on the body, the underclothing should be frequently changed, and warm baths should be taken to prevent reinfection.

Stock vaccines, and more frequently autogenous vaccines, have occasionally been found valuable. On the other hand, sometimes vaccines fail utterly to prevent the recurrence of boils.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

NORMAL HORSE SERUM (See N. N. R., 1918, p. 312).

The Gilliland Laboratories, Ambler, Pa.

Normal Horse Serum.—Marketed in syringes each containing 10 Cc.; also in ampules containing from 10 to 100 Cc. as ordered.

DIPHTHERIA ANTITOXIN, CONCENTRATED (See N. N. R., 1918, p. 314).

The Gilliland Laboratories, Ambler, Pa.

Gilliland's Concentrated and Refined Diphtheria Antitoxin.—Prepared according to Banzhaf's method and preserved with 0.4 per cent. trikresol, contains less than 20 per cent. of solids. Marketed in syringes containing each 1,000, 3,000, 5,000, 7,500, 10,000, 15,000 and 20,000 units.

TETANUS ANTITOXIN, CONCENTRATED (See N. N. R., 1918, p. 315).

The Gilliland Laboratories, Ambler, Pa.

Gilliland's Concentrated and Refined Tetanus Antitoxin.—in syringes containing each 1,500, 3,000 and 5,000 units.

THE REGULAR MEDICAL CORPS—AN OPPORTUNITY

This is a call to the young medical men of America, to the men not yet established and who are seeking a career. The United States Army Medical Corps has eleven hundred vacancies; officers for six hundred and fifty of these are urgently needed now. It is not a sacrifice — the men who can answer this call are in any event practically within the draft age. It is a call to them to choose the Army medical service, not as a temporary vocation, but as a career. Today probably every young physician gives some thought to this choice. Few, however, consider the opportunity with a full knowledge of its advantages.

The medical officer is not only a physician, but a soldier. He has a double function and a double responsibility. The history of our Army medical department is full of examples of men who have fulfilled their responsibilities gloriously. The organization to which the young men are called is one of magnificent traditions, of scientific accomplishment, of transcendent present importance. It offers a position of regular employment, of fixed equable income, of steadily increasing ability, importance and emolument, of opportunity for individual study and recognition. The requirements for admission and the training of the men in the corps, the rank as an officer, insure a most desirable social atmosphere. There is association with well educated, scientific, progressive men and an absence of the petty social jealousies of civil life. The man who is personally fit can go far and achieve much.

The essential requirements are: (1) citizenship, (2) age between 22 and 32 years, (3) graduation from a well-recognized medical school, (4) one year's hospital internship, and (5) good moral character and habits. Applicants must pass an examination not difficult for men who can meet the other requirements. If successful they receive a three months' training course with full pay and allowances.

This is a call first, to men who are not now in the Medical Reserve Corps, and second, to the younger Medical Reserve Corps officers. The first class have not done their duty by themselves or by their country. The second class have shown their patriotism and are no doubt already in the service or completing internships and awaiting call. They have been permitted to "sample the goods before purchasing." To them especially the service should appeal as a career. They too may make application for examination and transfer to the Regular Medical Corps. The Army and the nation need these men now. It does not ask of them the tremendous sacrifices made by the older men who have given up their homes, families, incomes, and perhaps their careers; it offers an established income and an enviable position.[1]

YOUNG MEN, THIS IS YOUR OPPORTUNITL; SEIZE IT!

GASES IN MODERN WARFARE

Despite the fact that the daily newspapers frequently report the use of poisonous gases in the conduct of the war on the European continent, few physicians understand much more about the methods employed, the substances used, the protections devised and the untoward effects encountered than does the layman who carefully follows the reports from the centers of conflict. After all, this is not strange. Gas warfare is an innovation in the struggle between armies. It seemed so unlikely in 1914 that any enemy would introduce this atrocious form of attack that when the first reports of the preparation to employ it reached the allied forces they were scarcely credited, and no serious notice was taken of the information. With the initiation of the first gas attacks by the Germans in 1915, modern modes of conducting war were radically modified.

The story of the varied types of this hellish performance, of how the unexpected was met and mastered, of the frequently altered forms and phases of gas warfare conducted with the aid of skilled engineers, technologists and chemists has scarcely traveled beyond the trenches. It has been full of surprises; replete with difficulties such as confront the student of new diseases; and, if we may forget the awful horror of the consequences, the use of gases has formulated questions of broad scientific import. However terrifying the prospects may be, we must realize that a new and deadly weapon has been used, and its entrance into the arena must be reckoned with by the application of skill and knowledge.

What is the deadly gas, and how is it used? To this the answer may be made that there already are literally a score of harmful gases used in more than one way that have attained some notoriety.[1] First used and best recognized in medical circles was chlorin gas. This is sent out as a cloud from cylinders concealed beneath the parapets. The wind must be of suitable velocity and direction to make the attack effective. Protection is afforded by a respirator which causes the gas-laden air breathed to pass through an absorbent soaked in solutions of alkali carbonate or thiosulphate. The next surprise came in the form of carbonyl chlorid, or phosgen ($COCl_2$), an insidious gas difficult to protect against. Fortunately, a partial protection was soon found in helmets saturated with sodium phenate. It became apparent, to quote a military expert, that three things really matter in gas warfare, and these were all emphasized at this early period. They are (1) increased concentration of the gases used, so that the protective devices no longer suffice; (2) surprise attacks, whereby the troops are gassed before there can be made adequate provision for protection, and (3) the use of unexpected new materials.

---

[1] Circular of information and application will be sent by The Journal on request.

Accordingly, when carbonyl chlorid began to be used by the Germans in increased concentration, further provision to meet this became necessary. Here chemical ingenuity suggested the use of hexamethylenamin in conjunction with sodium phenate. On the horror of gas clouds the frightfulness of gas shells presently was superimposed. They are asserted to be the most important of all methods of using gas, and are still in the course of development. The widely proclaimed "tear" gases were delivered in this fashion. Originally xylyl bromid or benzyl bromid, obtained by bromination of the higher fractions of coal-tar distillates, formed the contents of the "tear" shells. A concentration of some of these lacrimators in the proportion of one part in a million makes the eyes water severely. The enormous extent to which such chemical products have been employed is indicated by the fact that the Germans have put down heavy barrages of "tear" gas shells. In 1916, such highly poisonous substances as trichloromethyl-chloroformate were included, the attempt often being made to increase the concentration by the mode of shelling so that some of the gas would pass through the protective helmets, as it actually did at times. Hence we can understand Auld's contention regarding the significance of suitable protective devices. "Respirators," he says,[1] "have to fulfil two requirements which are quite opposed to one another. In the first place they should be sufficiently large and elaborate to give full protection against any concentration of any gas, whereas military exigency requires that they be light and comfortable. It is necessary to strike a balance between these two. Upon a proper balance depends the usefulness of the respirator. Oxygen apparatus will not do on account of its weight and its limited life. Two hours' life is excessive for that type. The side that can first force the other to use oxygen respirators for protection has probably won the war."

Last summer witnessed the beginning of the use of a still more harassing gas. An added lacrimator in the form of phenyl carbylamin chlorid has been tried; then came the celebrated "sneezing" gas, diphenyl-chloroarsin, intended to make a soldier sneeze so badly that he will be unable to keep his mask on. But the surprise that scored heavily in 1917 was the "mustard gas," dichloro-diethylsulphid. As many as 50,000 shells containing this "superlacrimator" have been reported as fired in a single night's bombardment. The effect is most insidious. The gas has a distinctive smell, rather like garlic than mustard. It has no immediate effect on the eyes, beyond a slight irritation. After several hours the eyes begin to swell and inflame and practically blister, causing intense pain, the nose discharges freely, and severe coughing and even vomiting ensue. Direct contact with the spray causes severe blistering of the skin, and the concentrated vapor penetrates the clothing. The respirators, of course, do not protect against this blistering.

In passing, we may recall the German hand grenades filled with bromin, chloracetone, chlorsulphonic acid, sulphur trioxid or dimethyl sulphate—surely a ghastly array! If the "colorless, odorless, invisible and highly poisonous" gas has not yet come to the front, its near relatives have nevertheless been in evidence. Meanwhile, the chemical laboratories of the Allies have not been idle.

THE HOUSE FLY AND BACTERIA

With the approach of the summer season the annual problem of the fly and its possible menace to health and comfort is presented for serious consideration. Despite the enthusiasm with which the antifly campaigns have been launched in various localities within the past few years, there are many persons who question seriously whether the effort and expense inevitably involved are worth while when considered primarily from the standpoint of the public health. There can be little question that the fly is a nuisance and deserves to be eliminated from the neighborhood of human habitations on grounds of comfort and cleanliness, if not on the basis of danger to health. With respect to the latter aspect of the subject there is no overabundance of evidence as clearcut as now exists with reference to the noxious mosquito. Decisive facts are therefore always to be welcomed.

The common house fly, *Musca domestica*, can transport bacteria in a variety of ways. The micro-organisms may adhere mechanically to the surface of the body, legs, wings and proboscides of the insects; or the insects may carry them in the intestinal tract and deposit them on foods either in the fecal discharges or in the regurgitated food of the so-called "vomit spots." Among the facts that appear to be reasonably well established is a seasonal variation in the number of bacteria carried. The greatest bacterial flora is apparently coincident with the summer months. That locality may play a part in the numbers of micro-organisms is indicated by the investigations of Cox, Lewis and Glynn,[1] and more recent studies in the District of Columbia.[2] Flies caught in the insanitary or congested areas of Liverpool carried greater numbers of bacteria than flies obtained in the more sanitary, less congested districts. Similarly, flies captured in the residential section of Washington were reported to carry fewer bacteria than the insects obtained from cheap restaurants in the business districts of the city. Still less bacterial contamination was observed in flies caught in the open country near the capitol city.

---

[1] The basis for this statement and others pertaining to the subject is taken from the report of an interesting lecture by Major S. J. M. Auld of the British Military Mission, as published in the Journal of the Washington Academy of Science, 1918, 8, No. 3.

The possibility of the transmission of harmful micro-organisms has also been established. The cholera bacillus was detected on flies as early as 1886; the bacillus of tuberculosis was found in 1888; that of bubonic plague in 1894; of typhoid fever in 1903. Indeed, during an epidemic of typhoid in Chicago, Hamilton[3] detected typhoid bacilli in five out of eighteen flies that were caught. The list of such findings might be considerably extended. Scott,[2] the microscopist of the Army Medical Museum in Washington, who has made numerous bacteriologic examinations of flies in that locality, reports that the isolation of members of the colon-typhoid-dysentery group of bacilli from numbers of flies indicates that the house fly has the power of carrying the closely allied pathogens, typhoid and dysentery. However, despite the evidence for the contamination of the house fly by the fecal discharges of man and animals, the results of Scott's experiments indicate that typhoid fever in the District of Columbia, under normal conditions, is not referable to the agency of this insect.

The finding of pyogenic cocci on flies by Scott, as well as by a few others before him, furnishes a suggestion of potency for harm. It indicates that the insect may be an agent in the dissemination of suppurative organisms from man to man. Herein, too, says Scott, may lie one explanation of the spread of gangrene in field hospitals under war conditions. A specifically noteworthy accomplishment in the study of the bacteriology of the house fly was Scott's[4] recovery of *Bacillus cuniculicida,* the causative organism of a septicemia in rabbits and guinea-pigs. This helps to explain the sudden outbreaks and spread of certain epidemics among laboratory animals. It emphasizes the necessity for proper screening of windows and doors where experimental animals are kept, and particularly calls for protection from the house fly in cases in which they are inoculated with pathogenic organisms. It is such facts, furthermore, that argue not only for protection of food and persons against flies, but even more for the abolition of the breeding places of these insect pests.

Current Comment

OUR COUNTRY'S CALL

When our country entered the war the American Medical Association placed its services at the disposal of the Government: its entire machinery, its publication and its total resources — the state and county societies with their 81,000 members — for the purpose of organizing the medical profession for the war. To previous calls the profession has responded splendidly. We are confident that the same ready response will be made to this new call for 5,000 additional medical officers. The matter is considered in greater detail in the report of the action of the War Committee of the Association elsewhere in this issue.[1] No one can prophesy what the duration of the war will be; it may be three years, it may be five years; it may demand three million or five million fighting men. But whatever may be the needs to secure victory, they will be supplied. And the medical profession will do its part. In Great Britain and in France the demands required drafting of all able-bodied men — even those past middle life; and this included the medical profession. While a similar draft on the manhood of this country may have to be made, we do not believe that it will be necessary to include the medical profession, for physicians will do voluntarily whatever they are called on to do. However, the time has come for deeds, not words; for action, not promises; for accomplishment, not prophecy. The time has come for every medical man under 55 years of age, who is physically qualified, to consider seriously for himself the question of his duty to his Government. In doing this, each one must realize that practically all who have thus far volunteered have done so at a sacrifice: in some instances the sacrifice has been small; in others, great. Patriotism and one's sense of duty to one's country have been the motives that have prompted the action of those who have joined the Medical Reserve Corps. This has been especially true when action meant sacrifice. That same spirit must and will prevail now.[2]

PROTECTIVE INOCULATION AGAINST LOBAR PNEUMONIA

While recent investigations have added much to our knowledge of the pneumococcus, a successful method of antipneumococcus inoculation, naturally sought for because of the frequency and the high death rate of pneumonia, has remained unattained. Certain early efforts failed mainly, it would seem, because the essential importance of the different immunologic groups of the pneumococcus was not taken into consideration. More recent work by Lister in the diamond mines at Kimberley, South Africa, promises better results. Lister, who independently worked out the differentiation of pneumococci into several distinct groups by means of immune reactions,[1] his grouping being not quite the same as that of Dochez and Gillespie, finds that the pneumonia prevalent among the workers in the diamond mines is due mainly to three groups of pneumococci,[2] and that three subcutaneous inoculations with a triple vaccine of the three groups prevents the occurrence of pneumonia as caused by members of these groups, but not the pneumonia due to other groups of pneumococci. From seven to ten millions of pneumococci were given at each injection, the cocci being first killed by a germicide and not by heat. The fact that Lister apparently has succeeded in preventing pneumonia caused by the pneumococcus groups of which his triple vaccine was made is certainly worthy of serious consideration. The suggestion lies near at hand that prophylactic inoculation with the prevailing groups of pneumococci should be given a thorough trial where large numbers of susceptible persons are aggregated under conditions that usually favor the outbreak of pneumonia.

THE PURIFICATION OF SWIMMING POOLS

The secretary of the American Association for Promoting Hygiene and Public Baths, Dr. Manheimer,[3] has thus summarized his objections to the various methods of disinfection for pools employed heretofore: Ultraviolet light in actual practice has proved ineffective; copper sulphate in low dilutions is unreliable, and in high concentration is not only costly, but also produces a water disagreeable to swim in; chlorin compounds, while effective as disinfectants, require a technical control usually not available in swimming pools, and when used in excess produce objectionable taste and odors in the water. As the result of Manheimer's investigations at the Research Laboratory of the Department of Health, New York City, he has reached the conclusion that ozone properly applied to the water of a swimming pool effectively purifies the water. When one part of ozone per million parts of water is used, the result is sterile water. When one half part of ozone per million parts of water is used, a bacterial reduction of 99.8 per cent. results, except when too great an excess of air is introduced with the ozone. The application of the ozone for such purposes is said to be automatic in control, reliable in action, and not unduly expensive, so that the New York report recommends the consideration of this substance for use in a standard sanitary purification of swimming pools. Wherever recirculation of water is resorted to, as usually is the case for purposes of economy, refiltration must, however, be combined with the disinfection procedure. Manheimer points out, what is not generally understood, that clear water is essential, not mainly because of esthetic reasons, but for the reduction of the hazard of drowning. No method in actual practice, he adds, measures up to refiltration. It is an open question whether Manheimer's rejection of disinfectants other than ozone is based on adequate data. Both ultraviolet light and chlorin compounds are giving satisfactory bacterial and esthetic results with certain swimming pool waters. While certain advantages of ozone are manifest, it does not seem wise to recommend ozone treatment to the exclusion of other methods. Manheimer's own published observations seem too limited to warrant extreme generalizations. The nature of the water dealt with and other local conditions are obviously factors to be taken into consideration.

"TRUTH IN ADVERTISING"

What is there about the "patent medicine" business that seems to make both those who are engaged in it and the newspapers that profit by it, throw truthfulness to the winds? Here, for instance, are some excerpts from advertisements that appeared a few days ago in a high-class newspaper, the Chicago *Evening Post:*

> "Famous Beauties Never Get Fat.—Womankind wonders why famous beauties grow old, but do not grow fat. They live at silken ease, amid the porcelain flesh pots. The wine, that puffs out obscure mortals, flows not illiberally down their alabaster throats. Yet their lifelong loaf does not thicken their limbs nor double their chins. What is the secret of the long-lived gracefulness of the haut-ton?"

The "secret" is "Marmola," which, we learn, has been "long familiar to the fashionable pharmacists of the world and their clientele, but which has only recently penetrated to the knowledge of the hoi polloi of womankind." "Marmola," as many of our readers know, according to analyses that have been made, has for its active and essential drug, thyroid extract.

> "With this tablet any woman can reduce, be losing a pound a day, in a few weeks; take off fat (where it shows most) on chin, abdomen, hips, etc., without need for exercising, table restraint, fear of wrinkles, or the slightest physical harm or uneasiness."

Feminine readers of the *Post*, then, are assured that they may indulge in a "life-long loaf," may drink alcoholics "not illiberally," may abandon "table restraint" — all without fear of becoming obese, provided they, "the *hoi polloi* of womankind" follow the methods "of the *haut-ton*" and rely on Marmola! The fat woman is told that she can reduce her weight "a pound a day" and can "take off the fat where it shows most" — if she will take Marmola! As a specimen of condensed mendacity and misinformation this Marmola advertisement is a gem. The publishers of the *Post*, of course, do not know the dangers of thyroid extract self-administered in ignorance of its presence; but surely the absurdity, if not the falsity, of the claims made in the advertisement must be patent to any but the most credulous. One is led to speculate on the effect such advertisements as this have on the readers of the *Evening Post* — for the *Post* is a paper whose clientele is above the average in intelligence. One wonders, too, to what extent the public's confidence in the really meritorious products, advertised in the same paper, is undermined.

BACTERIA AND VITAMINS

That the food accessory factors now familiarly spoken of as vitamins may have some part to play in relation to the immunity of the body from disease, or its susceptibility to invasion by micro-organisms, is suggested by a variety of known facts. One striking illustration is found in the tendency for the development of xerophthalmia when the fat-soluble vitamin, such as occurs in milk fat or butter, egg yolk and cod liver oil, is missing from the diet. From recent investigations it seems probable that not only animals, but even the higher plants, may derive advantage for their growth and development from substances comparable with the vitamins that facilitate animal well-being and exert their potency even when extremely small amounts of the as yet unidentified compounds are added to the culture medium. Loeb and Northrop,[1] who have succeeded in cultivating flies in the absence of bacteria, have shown that these lower forms also apparently require some accessory substance to facilitate their development. Now we are told that even bacteria cannot thrive without the presence of factors which act in very small amounts and are not, by themselves, able to support growth. Lloyd,[2] in England, has called attention to the alleged rôle of vitamins in the growth of the meningococcus, concluding from her investigations that the primary cultivation of this micro-organism in vitro is possible only in the presence of certain accessory growth factors present in blood, serum, milk and other animal fluids, and probably also in vegetable tissues. She regards the essential substances as moderately stable toward heat. In this country, Davis[3] has offered further evidence that something comparable with vitamin phenomena may appear in bacterial nutrition. His attention has been directed to the growth of hemophilic bacteria which require hemoglobin for their development. For optimal growth, however, something more seems to be essential, and the added factor, not found in synthetic mediums, is found in foreign bacteria, and in fresh animal and plant tissues. How the substances thus furnished act is quite as obscure as is the answer to the question of their chemical nature. Davis suggests that they may function, in the case of hemophilic bacilli, to render iron more available; and he ventures the further suggestion that the action of vitamins in animals and higher plants may concern or somehow control the metabolism of certain elements like iron, phosphorus, calcium or iodin, as well as possibly the protein metabolism. It is perhaps too early in the period of collecting facts in this field of study and critically evaluating them to indulge in elaborate hypotheses; but the fascinating mystery of the vitamins is penetrating into many avenues of biologic inquiry. Science must guard against undue enthusiasm when so much uncertainty and contradiction still exist.

IMPROVEMENTS IN FOUR YEARS AT YALE UNIVERSITY SCHOOL OF MEDICINE

About five years ago, Yale University School of Medicine had acquired by gifts and bequests a total of less than $400,000 for endowments; it lacked suitable quarters for the clinical departments, and had only limited teaching facilities in the New Haven Hospital. A committee made a careful investigation, and a campaign for improvement was begun. A close affiliation between the medical school and the New Haven Hospital was secured through a generous gift from the Brady family, who gave $125,000 for the Anthony N. Brady Memorial Laboratory to be erected on the grounds of the New Haven Hospital. The Brady family also gave $500,000 for its endowment, subject to the raising of an additional $2,000,000 for the medical school. The General Education Board promised to add $500,000 to this sum, providing the main clinical departments were put on the full time basis, and numerous other gifts, ranging from small amounts up to $400,000, were made, so that recently President Hadley announced that gifts of over two and a half million dollars had been received. Of this sum, $125,000 was for the new laboratory building; the balance of the funds was to provide for instruction and research. Not only has the medical school greatly increased its endowment, therefore, but it has also provided a new laboratory building for pathology, bacteriology and pathologic chemistry, obstetrics and gynecology, and clinical medicine and, at the same time, has secured a teaching hospital by the closer relationship with the New Haven Hospital. Under the new arrangements the members of the attending staff of the hospital are appointed on the nomination of Yale Corporation. Incidentally, Yale University School of Medicine is doing its part in solving problems connected with the war. Its departments of physiology, pathologic chemistry and pathology, particularly, have been aiding the government in providing gas masks for the American troops and in conducting experiments leading to the reduction of fatalities from gas warfare. This country still has an abundance of medical schools, but there is always room for those which, like this, are amply endowed and equipped.

ANOTHER TESTIMONIAL SMASHED

This from the *Congressional Record* of April 6, Hon. William E. Mason of Illinois speaking:

> ". . . I have one rule of life, and that is never to get up mad in the morning. It is what keeps me well and a *little* stout. . . ."

And we thought it was "Nuxated Iron"!

The Surgeon-General's Appeal For 5,000 Additional Medical Reserve Corps Officers

The War Committee of the AMERICAN MEDICAL ASSOCIATION met at the Association building, Chicago, April 16, to consider and act on the proposition contained in the letter of the Surgeon-General of the Army addressed to the AMERICAN MEDICAL ASSOCIATION, and printed in THE JOURNAL last week, page 1100.

The committee, acting under the authority of the Board of Trustees, confirmed by the House of Delegates of the AMERICAN MEDICAL ASSOCIATION, in behalf of the medical profession of the United States, accepted the obligation. In undertaking to secure the additional 5,000 physicians, the Association confidently anticipates the hearty, active, patriotic coöperation of the officers of every state association, the councilors of every district and of the officers and members of every county society, as well as of every loyal physician, whether a member of the organization or not.

As stated in his communication, it is the desire of the Surgeon-General that the securing of these additional 5,000 medical officers shall be accomplished without serious hardship "upon any community, manufacturing concern, or other civil activity by taking from such community, manufacturing concern or other civil activity physicians whose services are needed for the efficient and competent care of the civil population or the employees of large concerns." It is necessary, therefore, as a preliminary, that the actual conditions existing in all parts of the country shall be known: the number of physicians who have already accepted commissions and the number still available in every community. This requires a complete survey of the situation. Such a survey is in course of preparation and will be published within a short time as a supplement to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. It will include the names of those who have accepted commissions in the Army and in the Navy. These names will be listed alphabetically by states, counties and towns. The survey will also indicate the size of the county, the population, the number of physicians, the number under 55 years of age, and other important data. The information will be tabulated for each state by counties so that it can be seen at a glance what counties or communities have or have not furnished their quota. A similar tabulation of the data by states for the whole country will be included. This survey will provide a basis for active, intelligent, cooperative effort.

That there may be a full agreement as to procedure and complete harmony in all that is done in the various states, the committee desires the counsel and advice of the state associations. It has authorized, therefore, the calling of a meeting of the secretaries of state associations to be held at the Association headquarters in Chicago, April 30. This meeting will provide an opportunity for discussing the conditions existing in each state and of learning what, if any, modification of the proposed general plan of procedure will be necessary to secure practical results in every state.

Considering the whole problem of supplying not only the immediate but also the future needs, the committee deliberated on the advisability, or necessity, of calling for a voluntary draft of all physicians under 55 years of age. The proposition, briefly outlined, means that every physician in active practice shall volunteer as a member of the Medical Reserve Corps, and be subject to call for military or civilian activities as he may be qualified and as conditions and necessities may require. The committee deems this extreme measure unnecessary for the present at least.

In conclusion, it will be recalled that when our country entered the war, the AMERICAN MEDICAL ASSOCIATION formally and officially offered to the Government its services and facilities for such assistance as may be in its power to render. The Association now gladly and promptly undertakes this new task, acting for the national, state and county organizations including over 81,000 members, using THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, in short, its entire machinery, to assist in organizing the medical profession of the United States for the war.

In the meantime, while the proposed survey is being completed, and arrangements are perfected for a genral, systematic appeal addressed especially to those communities whose physicians have not yet made application for commissions in the Medical Reserve Corps in accordance with the average quota, every physician, individually, should consider carefully his personal responsibility. If it is possible for him to do so he should make application at once for a commission.

NOTE.—An application blank and a list of the examining boards will be sent by The Journal on request.

Medical Mobilization and the War

Honor for Surgeon-General Goodwin

It is announced that the King has appointed Major-Gen. (temporary lieutenant-general) Thomas H. J. C. Goodwin, C. M. G., D. S. O., director-general of the army medical service to be an additional member of the military division of the third class, or Companions, of the Most Honorable Order of the Bath.

Medical Officers Wounded in Action

The following medical officers are reported as recently wounded in action: Lieuts. Daniel H. Lawler of Baltimore, Samuel Miller of Manchester, N. H., and William Michel of Frostburg, Md., on the British front during the recent drive of the Germans.

"Fit to Fight"

A film entitled "Fit to Fight" has been prepared through cooperation between the Army Medical Department, the War Department, the American Social Hygiene Association, the Commission on Training Camp Activities, and the Metro Picture Corporation. The photographic and laboratory work has been done by the Army Medical Museum. The film is a part of the campaign to combat venereal diseases. It is now being shown in the cantonments. Requests for the use of the film are being received by the Medical Department from educational institutions, and will be responded to as promptly as possible.

The Incidence of Venereal Diseases

The Surgeon-General has issued a statement relative to the number of cases of venereal disease in various parts of the Army. The annual rate for the forces in France is 44.2 per thousand. If the number of cases of venereal disease during the week ending Sept. 28, 1917, were continued for the whole year, the number per thousand men for the three armies would be: Regular Army 80.5, National Guard 149.2, and National Army 387.6. The best rate made by our regular Army prior to the war was the actual rate of 1916, of 91.23 per thousand. The best week in our present Army was that ending Dec. 14, 1917, when the annual venereal disease rate per thousand for our regular Army was 69.7, National Guard 44.6, and National Army 74.3. The worst week was that of Jan. 11, 1918, when the rates were: Regular Army 97.8, National Guard 89.9, and National Army 54.4.

Personnel of the Medical Department

For the week ending April 12, 1918, the personnel of the Medical Department of the Army included:

Medical Corps. 796, including 1 major-general, 66 colonels, 102 lieutenant-colonels, 198 majors, 2 captains and 427 lieutenants.

Medical Reserve Corps: 18,583, including 1,156 majors, 4,368 captains and 13,059 lieutenants. On active duty: 15,759, including 1,054 majors, 3,878 captains and 10,827 lieutenants.

Medical Corps, National Guard: 1,211, including 16 lieutenant-colonels, 250 majors, 151 captains and 794 lieutenants.

Medical Corps, National Army: 106, including 3 brigadier-generals, 11 colonels, 84 lieutenant-colonels and 9 majors.

Dental Corps, 209, Dental Reserve Corps, 5,197, of whom 1,363 are on active duty; Dental Corps, N. G., 259; Veterinary Corps, 18; Veterinary Reserve Corps, 1,429, of whom 820 are on active duty; Veterinary Corps, N. G., 53; Veterinary Corps, N. A., 373; Sanitary Corps, 1,026, and Ambulance Service, 153, constitute the remainder of the commissioned personnel.

The DISCHARGES in all branches of service to date are:

Causes	Number M.R.C.	 M.C.N.G.	 D.C.N.G.	 San.C
Physical disabili	522	41	7	5
Inaptitude	206	15	0	1
Other branches of the service	429	61	7	59
Domestic troubles	51	1	0	1
Resignations	147	45	5	8
Needed by the community	37	1	0	0
Deaths	45	3	0	0
Dismissals	3	2	0	0

NEWS OF THE CANTONMENTS

Eighty-First Division, Camp Jackson, Columbia, S. C.

April 9, 1918.

If there was ever a transformation in a place, it is in the site occupied by Camp Jackson. Everything that is conducive to health—climate, soil, drainage, water—is found here; everywhere activity is increasing and more efficient. The health of the division is good. System and uniformity of action are increasing. The base hospital is expanding to 2,600 beds. There are Red Cross buildings, the Y. M. C. A., and the Hostess House. Officers' quarters are enlarged. Many new officers are arriving every day.

ROENTGEN-RAY SERVICE

Capt. Harrison A. Greaves of Philadelphia is chief of the roentgen-ray department. A powerful 10 kilowatt interrupterless machine, vertical and horizontal fluoroscopes, plate changers and gas and Coolidge tubes, and a localizer for foreign bodies in the eye are included in the excellent equipment. Hundreds of men have been examined for tuberculosis and heart lesions. Stereoscopic plates are made whereby the most delicate lesions of early tuberculosis may be detected. Nearly a thousand examinations of the teeth have been made for focal infection, filling defects before and after, abscesses, and impacted molars.

All the men referred by the various specialists, tuberculosis, medical, surgical, eye, ear, nose and throat, have been successfully examined.

PERSONAL

Major C. L. Roberts, commanding officer, has been promoted to lieutenant-colonel.——Major F. P. Quain of Bismarck, N. D., who organized No. 1 Base Hospital, Surgical Unit, is chief of the surgical service.——Lieutenant Van Korb, assistant in the roentgen-ray department, has been promoted to captain.——Capt. John W. McConnell, in charge of the ear, nose and throat section, has received his promotion as major.——Captain Meredith was promoted to major.——Capt. Reik, surgeon, of Baltimore, has been assigned to temporary duty as assistant in the ear, nose and throat section.——Major Walter Bensel has been promoted to lieutenant-colonel.——Major Thomas J. Burrage of Maine is assistant to Major Herrick in the medical service.——Capt. Carl Mitchell of Benton Harbor, Mich., is an assistant in the surgical service.——Lieutenant Scovell, chief dental surgeon, has been promoted to lieutenant-colonel.——H. Judson Lipes, major, M. R. C., Albany, N. Y., formerly a professor at Albany Medical College, is now on the surgical service at the base hospital, Camp Jackson.——Dr. Blanche F. Greaves, wife of Capt. Harrison A. Greaves, chief of the roentgen-ray section, who has been visiting Columbia at Dr. A. E. Shaw's beautiful and historic mansion, has returned to Philadelphia.

If one may speak of the moral and religious tone of an army in the making, Camp Jackson has it. Respect for authority, willingness to do the right thing, and avoidance of the wrong are seen throughout the whole cantonment. Everything from one end of the cantonment to the other is "'Tention!" Discipline, instant and willing obedience, and will to win the war for the freedom of the world are everywhere in evidence. Let every one in America from 16 to 60 save, serve and sacrifice. There is one way in which every one in America can help—buy Liberty Bonds! This is the way to save your home and your family from destruction and slavery.

Camp Zachary Taylor, Eighty-Fourth Division, Louisville, Ky.

April 15, 1918.

MAJOR BOARD EXONERATED

Exoneration of Major Milton Board, Medical Reserve Corps, a Louisville physician, who was charged with negligence as result of the death of Private Otha Murray, is announced in court martial orders made public yesterday at Camp Zachary Taylor. The court acquitted Major Board on all specifications of the charge against him and the acquittal is approved by Major-Gen. Harry C. Hale and the legal reviewing authorities. The specific charge against Major Board was that he "negligently and without due regard for the health and safety of Private Otha Murray, Three Hundred and Thirty-Sixth Infantry, recommended and obtained his discharge and sent him home to die." The court makes no comment on the case but simply finds that Major Board was not guilty of negligence in any particular.

SANITARY INSPECTOR NAMED

Upon recommendation of Lieut.-Col. William Smart, division surgeon, Capt. Charles E. Libby, Medical Reserve Corps, was appointed sanitary inspector at the field artillery range at West Point, Ky.

The medical attachment of the First Provisional Regiment (colored) is being organized.

DISEASED MEN REMAIN

Notice has been given by the Adjutant-General of the Army that venereal diseases are included in the list of communicable diseases which prohibit soldiers being sent from one station to another, whether it be to another camp or cantonment or a port of embarkation for transportation overseas. Medical officers are to examine all men before they are transferred or sent away from camps. No man having or suspected of having a communicable disease will be sent away from his station.

CUBICLE SYSTEM

On recommendation of this board appointed by Major-Gen. Harry C. Hale, the cubicle system has been adopted in the One Hundred and Fifty-Ninth Depot Brigade and 20,000 yards of muslin have been ordered to put the method into effect.

Experience has shown that most of the sickness starts in the depot brigade, where the incoming quotas are quartered. Every precaution has been taken to detect symptoms as soon as they develop and to prevent spread of the diseases, but it was deemed advisable to resort to even more stringent measures.

Three-foot screens will separate the cots of the men in barracks. At the mess tables screens will divide the center of the table so that if a man coughs his breath will not be inhaled by the comrade sitting opposite him. Men will be assigned to regular seats at tables and space will be left between each.

It is expected that this system will, to a large degree, check respiratory diseases. The recruits will be placed in groups of fifty and except when they are drilling in the open where fresh air will reduce to a minimum the hazard, the members of one group will not be permitted to associate with those of another group.

Should communicable diseases develop in a group the medical officers can quickly locate the source of trouble and remedy it. They will know exactly who has been exposed. These contacts will be moved to quarantined barracks. Capt. David M. Roberg is supervising the installation of the new system.

Another new method was [illegible] the contacts in the case of communicable [illegible]; after the discovery of a case of measles, diphtheria, scarlet fever, pneumonia, or spinal meningitis in an organization its commander will segregate the men who have slept on bunks contiguous to the sick man, those who have always sat next to him at mess and the men with whom he associated and send them with their bedding and kits to report at the headquarters of the first group, One Hundred and Fifty-Ninth Depot Brigade, where they will be assigned to quarters in these buildings, and there will be rigidly quarantined.

The cubicle system was introduced at the base hospital recently with good results.

In addition to this, every one in the observation ward at the base hospital, officers, attendants and patients, is required to wear a face mask, and the Red Cross has been working vigorously to supply the many masks needed to carry out this ruling.

The plan of having the men examined daily by medical officers of their outfits has reduced sickness to some extent, but the greatest benefit is that the ailments are diagnosed when the first symptoms appear and before the patients' condition has reached a serious state.

Medical officers are leaving nothing undone in their endeavor to safeguard the health of the soldiers. It has been found that many of the diseases are brought in by selects who come from various sections of Kentucky, Indiana and Illinois, and from all walks of life. Although the country boy is considered healthier and stronger than the city chap, he is more susceptible to many communicable diseases, because he is virgin material. Most persons reared in thickly settled places have mumps, chickenpox, measles and other "children's diseases" when young and are immune, while the selects from the country who escaped them in childhood easily contract these ailments.

STREPTOCOCCUS VIRULENCE

The results in the recent streptococcus hemolyticus pneumonias at the hospital remain very serious. In a series of ten cases nine died. Unfortunately the War Department has recently issued an order limiting necropsies to cases in which "military necessity" makes it essential it should be done, and then only on order of the commanding general. As a result of this order it has been impossible for these recent virulent cases to be studied as they should be studied. The probable explanation is the increased virulence of the organism after it has grown through successive generations, with the soldier as the medium.

The chiefs of the medical service of a number of base hospitals have recommended the annulment of this rule as to necropsies, so that these cases can be properly studied.

PERSONAL

Lieut.-Col. John H. Allen, after being exonerated by a court martial at Camp Zachary Taylor, is serving in the same capacity at the local camp as he did before the trial. Lieutenant-Colonel Allen is division surgeon and considered one of the ablest officers at the local camp. The result of the trial was received with satisfaction by his friends and he has received many congratulations on his complete exoneration. Testimony at the trial showed that Lieutenant-Colonel Allen is not only a proficient surgeon but a man of high character as well.——Lieut. Arad Shaper, Medical Reserve Corps, who has been stationed with the Six Hundred and First Engineers at Camp Laurel, Md., has been ordered to Louisville to report to the commanding general at Camp Zachary Taylor for duty in the base hospital, the War Department announced today.——Lieut. John K. Norton reported from Camp Greenleaf, Chickamauga, in compliance with a War Department order and was assigned as chief psychologic examiner at the base hospital.——The following medical officers are transferred to Base Hospital Unit No. 25 at Camp Sherman for duty: Capt. Charles H. Paul, First Lieuts. Charles E. Kiely, Merrick F. McCarthy and George I. Thatcher.

Eighty-Sixth Division, Camp Grant, Rockford, Ill.

April 8, 1918.

EXAMINATION OF NEW DRAFT

The following change has been made in the routine of examination of the newly drafted arrivals in camp: the regimental medical officers examine the men as usual, being immediately followed by members of the tuberculosis examining board under Major Wheaton, who examine the men in the same room. They reject all frank cases at once and refer suspicious cases to the special board. These examiners are followed by the cardiovascular examiners, under Captain Pardee, and by the neuropsychiatrists under Major Fell, with similar methods of procedure. The men who are to be examined further because of suspected defects are sent with Form 1010 to the base hospital for closer examination by the special examiners, who are the chiefs of the various services in the hospital. These officers make their report in the form of a second indorsement on Form 1010 and these forms then come to the division surgeon for final judgment, before going to the chief mustering officer.

Eighty-Ninth Division, Camp Funston, Fort Riley, Kan.

April 6, 1918.

REMEDIABLE DEFECTS

The various military organizations of the camp have been seriously handicapped in their work at times by men within their ranks who were physically unable to stand the pace of the average man, but yet were not enough disabled to be discharged from the Army. To remedy this condition there has been instituted at this camp, a remediable defects battalion. Any man, whom the medical officer may decide, after careful examination, to be unfit for full duty, but whose defects are remediable, is now placed in this battalion. After being placed in the battalion, a man is carefully gone over by the medical officers of the organization, and a routine schedule of work and exercise is prescribed for him. Also any shoe corrections, or things of similar character that are indicated, are furnished. As the man improves, it is hoped to change him from a group of one grade to a more advanced grade, the idea being to ultimately fit as many men as possible for full duty. When this is impossible, after a man has been thoroughly tried out, he will be recommended for whatever special duty the officers of the battalion may think him to be fitted for. Care will be taken to avoid over-fatigue. The results of this move will be watched by both Line and Medical Officers with a great deal of interest.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

From Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending April 5, 1918

1. ANNUAL ADMISSION RATE PER 1,000 (DISEASE ONLY):	
All Troops	1,685.1
